

Advanced Angular

WELCOME!

Allen R. Sanders
Senior Technology Instructor

Join Us in Making Learning Technology Easier

Our mission...

Over 16 years ago, we embarked on a journey to improve the world by making learning technology easy and accessible to everyone.

...impacts everyone daily.

And it's working. Today, we're known for delivering customized tech learning programs that drive innovation and transform organizations.

In fact, when you talk on the phone, watch a movie, connect with friends on social media, drive a car, fly on a plane, shop online, and order a latte with your mobile app, you are experiencing the impact of our solutions.

Over The Past Few Decades, We've Provided

Over
62,300,000
expert-led learning hours

In 2019 Alone, We Provided

Training to over
13,500 engineers

Programs in
30 countries

Over **120** active trainers, with an average of over two decades of experience each.

Technologies we cover

Develop
Intelligence

React Native

AND MANY OTHER TRENDING TECHNOLOGIES

World Class Practitioners

250 best selling books authored

EXPERT PRACTITIONERS

9+ years of training experience

SEASONED CONSULTANTS

150 speaking engagements at industry conferences

Over 62 million practitioner led training hours

ENGAGING INSTRUCTORS

Over 17 years of industry experience per instructor

125 certifications in leading technologies

95% instructor satisfaction

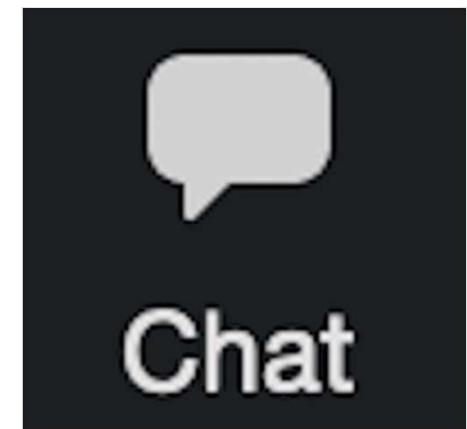

Virtual Training Expectations for You

Arrive on time / return on time

Mute unless speaking

Use chat or ask
questions verbally

Virtual Training Expectations for Me

I pledge to:

- Make this as interesting and interactive as possible
- Ask questions in order to stimulate discussion
- Use whatever resources I have at hand to explain the material
- Try my best to manage verbal responses so that everyone who wants to speak can do so

Quick review of key Zoom features that may be helpful for our course

Purpose

- Solidify a foundation in modern Angular
- Deepen understanding of the framework through advanced topic coverage
- Leverage instruction and practical exercise for reinforcement
- Topics include modules, components, directives, pipes, services, routing, forms and testing

Objectives

Upon completion of this course, you should be able to:

- Interpret and apply the advanced concepts of Angular
- Utilize the Angular Command-Line Interface (CLI) for app management
- Build a web application using Angular

Target Audience:

- Web developers with experience in UI dev looking to expand into more advanced areas of the framework
- Web developers with experience in back-end dev looking to establish complementary expertise in UI dev using Angular

Let's Get to Know One Another

Tell me about you:

- Name
- Current role
- How long you've been at the company
- How long you've been using Angular
- What's one thing you're hoping to get out of this course?

I'll tell you a little about me...

Introduction

Angular Features

- TypeScript-based open-source web application framework
- Application structure built around a hierarchy of modules and components
- Supports SPAs (Single Page Applications) using both template-driven and reactive forms
- “Separation of concerns” architectural pattern

Angular Features

- Feature-rich application scaffolding support via Angular CLI
- Includes several types of programmatic elements for use in our apps
- Integrates well with many different types of IDEs
- Uses Node.js (for JavaScript runtime), npm (for package management) and Webpack “under the hood” (for bundling)

Semantic Versioning

- Angular versions have included AngularJS and Angular
- AngularJS (aka Angular 1) did not use semantic versioning
- Angular 2 introduced the semantic versioning concept
- Now, instead of referring to Angular 2 vs. Angular 4 vs. Angular 10, we just call it Angular

Semantic Versioning

- Built around the concept of patch, minor and major change tracking
- Correspond to 3 different types of possible change to the framework
- Format:

Changelog available at <https://github.com/angular/angular/blob/master/CHANGELOG.md>

Patch Change

- Rightmost digit in version number incremented
- Usually implies a bug fix
- When upgrading, represents relatively low risk

Minor Change

- Middle digit in version number incremented
- More significant change or new functionality added
- However, should remain backward compatible on upgrade

Major Change

- Leftmost digit in version number incremented
- Represents most significant type of change
- Potentially incompatible with previous versions

Semantic Versioning & Testing

- Whether a major, minor or patch change, it's still a change
- Changes require testing to assess regression
- Points to the need for a robust set of automated test suites
- Which we'll be discussing when we get to the unit testing topic...

Angular – Up & Running

Node.js

- JavaScript runtime built on top of Chrome's v8 JS engine
- To install, navigate to <https://nodejs.org> (for Windows or macOS)
- For Linux, you can use *sudo apt-get install nodejs*
- Run *node -v* in your terminal to confirm (requires current or LTS version)

```
sysadmin@DESKTOP-QJENT2P:~$ node -v
v10.19.0
sysadmin@DESKTOP-QJENT2P:~$
```

Node Package Manager (npm)

- Software package manager included by default in Node.js
- Run *npm -v* in your terminal to confirm
- Provides scripting access to packages in a central npm registry
- “package.json” and “package-lock.json” list runtime and dev dependencies (with versions) for our Angular app

```
sysadmin@DESKTOP-QJENT2P:~$ npm -v
6.14.10
sysadmin@DESKTOP-QJENT2P:~$ -
```

Node Package Manager (npm)

- *npm install <packagename>[@version]* to download and install a package
- -g flag used for global install; otherwise, installs to local “node_modules” folder
- --save-dev flag used to indicate dev dependency
- *npm install* used to install all “package.json” packages

Angular CLI (ng)

- Key part of the Angular development and deployment toolset
- Used to scaffold a new Angular app
- Also used for scaffolding new Angular artifacts
- Includes commands for building, launching and deploying apps

Angular CLI (ng)

- Run *npm install -g @angular/cli* to install
- Run *ng version* to confirm
- General command format is *ng <command> [options]*
- *ng help* provides list of available commands and *ng <command> --help* provides help for a specific command

```
sysadmin@DESKTOP-QJENT2P:~$ ng version
Angular CLI: 11.0.5
Node: 10.19.0
OS: linux x64

Angular:
...
Ivy Workspace:

Package           Version
-----
@angular-devkit/architect    0.1100.5 (cli-only)
@angular-devkit/core         11.0.5 (cli-only)
@angular-devkit/schematics   11.0.5 (cli-only)
@schematics/angular          11.0.5 (cli-only)
@schematics/update           0.1100.5 (cli-only)

sysadmin@DESKTOP-QJENT2P:~$
```

Angular CLI (ng) – Common Commands

- *ng new* (or *ng n*) – Creates/scaffolds a new Angular app
- *ng build* (or *ng b*) – Compiles Angular app and outputs generated/bundled files to predefined folder
- *ng generate* (or *ng g*) – Creates/scaffolds a new Angular artifact

Angular CLI (ng) – Common Commands

- *ng serve* (or *ng s*) – Builds and serves Angular app from a preconfigured web server
- *ng test* (or *ng t*) – Runs unit tests for an Angular app
- *ng deploy* – Optimizes, bundles and deploys Angular app to web hosting provider

Angular CLI (ng) – Common Commands

- *ng add* – Installs a 3rd party library to an Angular app
- *ng update* – Updates an Angular app along with its dependencies

Visual Studio Code (IDE)

Visual Studio Code

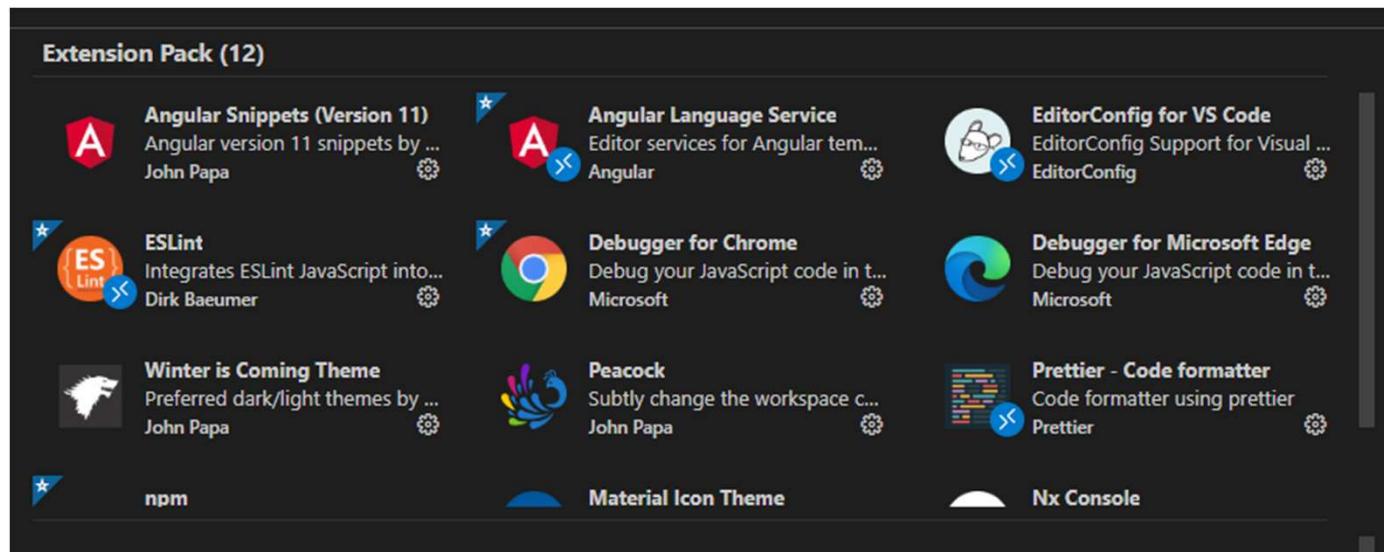

- While not the only option, VS Code is a great IDE for Angular development
- Cross-platform and extensible
- With the right extensions installed, can greatly facilitate Angular dev
- Access <https://code.visualstudio.com/Download> to download & install

Angular Essentials Extension Pack

- Represents a pack that includes several useful extensions
- Integrates intellisense, linting and formatting into HTML, CSS and TypeScript
- Provides debugging support for multiple browsers
- Provides code snippets that can be used to “jump start” your coding

Exercise 1

Spend a few minutes confirming your environment. Verify node, npm, Angular CLI and IDE. Create a new app and a new component. Add the new component into your root component and test using ng build and ng serve --open.

Environments

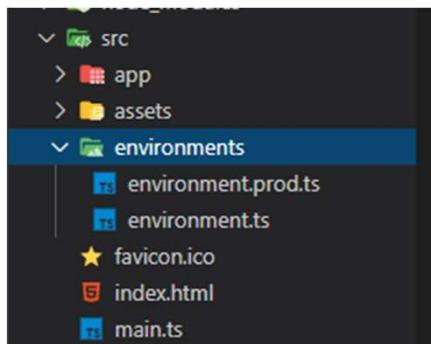

Environment-Specific Configuration

- Angular allows definition of environment-specific configuration
- At build time, a specific configuration can be applied
- Enables definition of things like back-end API URLs that vary by environment
- Defined as config objects in the “./src/environments/” directory with environment-specific file naming

```
environment.prod.ts X
src > environments > environment.prod.ts > environment > BASE_API_URL
1  export const environment = {
2    production: true,
3    BASE_API_URL: 'https://prod-server/api/my-api/'
4  };
5
```

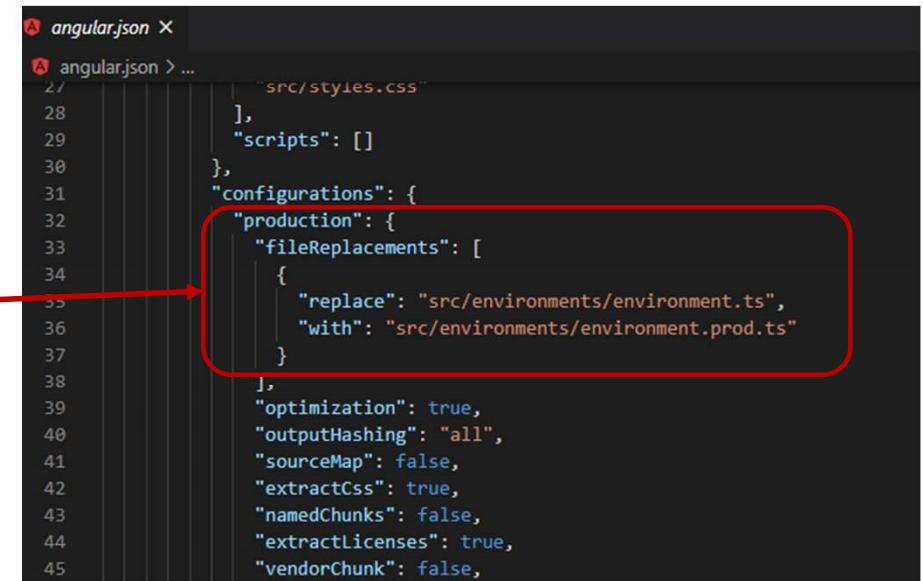

Environment-Specific Build

- To target an environment, run *ng build --configuration <envname>*
- Possible values for <envname> can be found in “./angular.json”
- Used to specify config file that corresponds to the target environment
- *ng build* will target dev (by default)

ng build --configuration production

```
angular.json
{
  "compilerOptions": {
    "src": "src",
    "outDir": "dist"
  },
  "styles": [
    "src/styles.css"
  ],
  "scripts": []
},
"configurations": {
  "production": {
    "fileReplacements": [
      {
        "replace": "src/environments/environment.ts",
        "with": "src/environments/environment.prod.ts"
      }
    ],
    "optimization": true,
    "outputHashing": "all",
    "sourceMap": false,
    "extractCss": true,
    "namedChunks": false,
    "extractLicenses": true,
    "vendorChunk": false
  }
}
```

Odds & Ends

Angular Ivy

- Angular's next-generation compilation and rendering pipeline
- As of Angular 9, used by default in Angular apps
- Advantages include:
 - Generated code that is easier to read/debug at runtime
 - Faster re-builds
 - Improved payload size
 - Improved template type checking

Angular Ivy

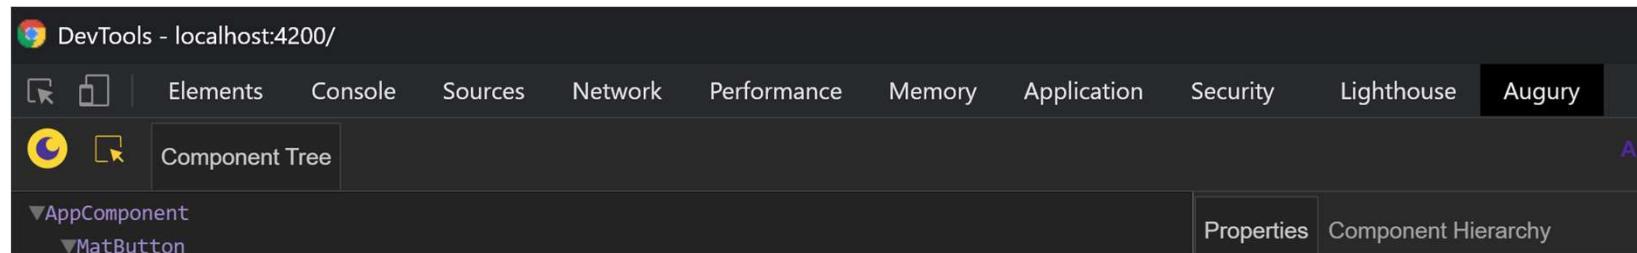

- AOT (ahead-of-time) compilation with Ivy will be faster
- You will also see performance improvements at runtime for prod builds
- AOT and Ivy will be enabled by default (for 9+)
- More info at <https://angular.io/guide/ivy>

Angular Augury

- Dev tool extension available for Chrome and Firefox
- Interactive visualizations offer insight during debugging
- To install, access <https://augury.rangle.io/> and choose “Install on Chrome” or “Install on Firefox”
- In a browser dev tool session, will show up as a tab for Angular apps

Angular Augury

- Component Tree displays loaded components in the app
 - Also displays hierarchical relationship between components
 - Includes detail on change detection, state and dependencies

The screenshot shows the Angular Component Tree and Router Tree inspector. The left sidebar lists components and routes:

- a (text="NgModel Form", url="#)
- li
 - a (text="InputOutput", url="#)
- li
 - a (text="Router", url="#/start")
- li
 - a (text="TodoApp", url="#/todo")
- li
 - a (text="DITree", url="#/di-tr")
- li
 - a (text="AngularDirectives", u")
- li
 - a (text="ChangeDetection", url="#/cd")
- li
 - a (text="StressTester", url="#/stress-tester")
- li
 - router-outlet
- InputOutput
 - Counter
 - div
- li
 - a (text="MetadataTest", url="#/meta-test")

The "Properties" tab is selected in the top right. The "Counter" component is highlighted. The "State" section shows the following state values:

- @Input() count: 0
- @Output() result:
- @Output() displayMessage: Huzzah! ✓

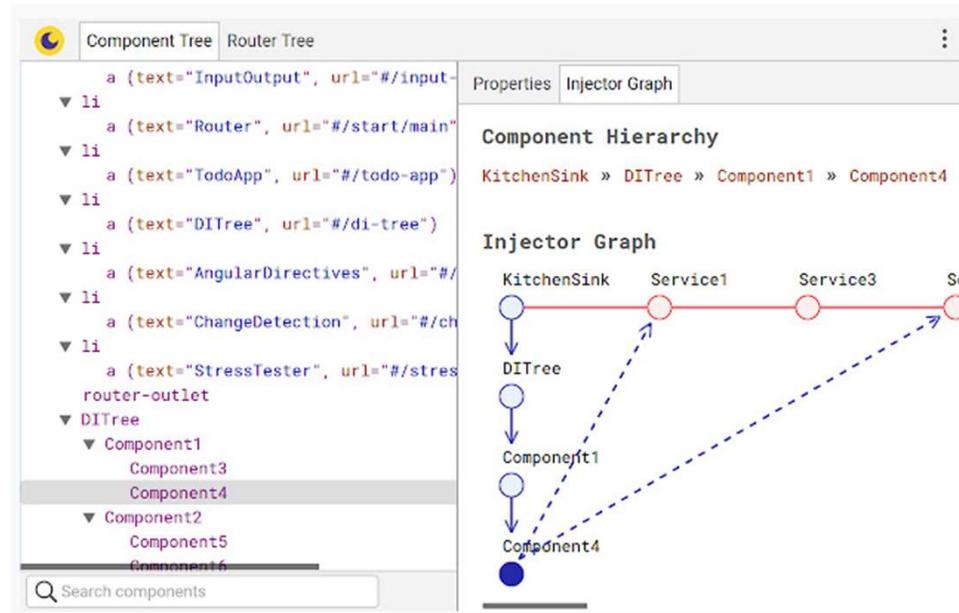

An "Emit" button is located at the bottom right of the state section.

Angular Augury

- Injector Graph displays a different view of hierarchy
- Includes info on how dependencies are injected & managed
- Provides visuals for both parent/root and component-level injection

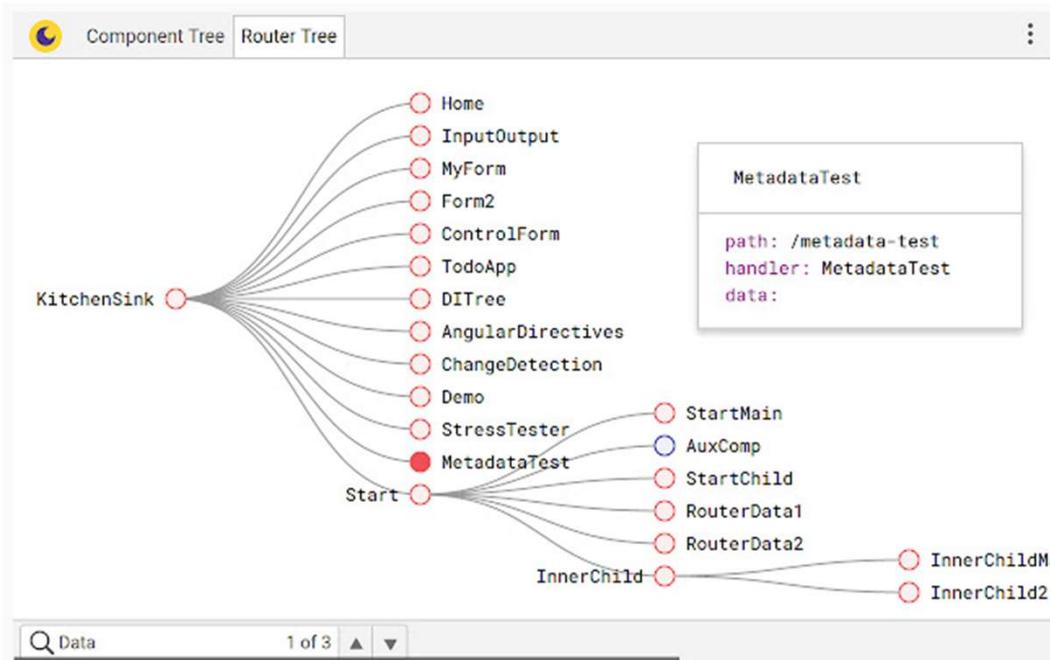

Angular Augury

- Router Tree displays routing information across the components
- For an app with Angular routing enabled, can assist with visualizing flow
- Supports both eagerly and lazy-loaded routes

Angular Modules

Bootstrapping an Angular App

- The process by which an Angular app is started
- Begins in “main.ts”
- Bootstraps the main module (called *AppModule* by convention) targeting the browser

```
main.ts  X
src > main.ts > ...
1  import { enableProdMode } from '@angular/core';
2  import { platformBrowserDynamic } from '@angular/platform-browser-dynamic';
3
4  import { AppModule } from './app/app.module';
5  import { environment } from './environments/environment';
6
7  if (environment.production) {
8    enableProdMode();
9  }
10
11 platformBrowserDynamic().bootstrapModule(AppModule)
12   .catch(err => console.error(err));
13
```

Bootstrapping an Angular App

- On startup, browser loads “index.html” (which likely contains an `<app-root>` element)
- The search for a matching selector in the component tree hierarchy begins

```
5  index.html ×  
src > 5  index.html > ...  
1    <!doctype html>  
2  ✓ <html lang="en">  
3  ✓ <head>  
4    <meta charset="utf-8">  
5    <title>FirstApp</title>  
6    <base href="/">  
7    <meta name="viewport" content="width=device-width, initial-scale=1">  
8    <link rel="icon" type="image/x-icon" href="favicon.ico">  
9  </head>  
10 ✓ <body>  
11  ✓ <app-root></app-root>  
12  ✓ </body>  
13  ✓ </html>  
14  |
```

Bootstrapping an Angular App

- *AppModule* (the main module) will include a reference to the main component (called *AppComponent* by convention)
- *AppComponent* will define a selector and template for *<app-root>*
- Angular will replace the selector with the template and continue parsing

```
app.module.ts ×  
src > app > app.module.ts > ...  
1 import { BrowserModule } from '@angular/platform-browser';  
2 import { NgModule } from '@angular/core';  
3  
4 import { AppComponent } from './app.component';  
5  
6 @NgModule({  
7   declarations: [  
8     AppComponent  
9   ],  
10  imports: [  
11    BrowserModule  
12  ],  
13  providers: [],  
14  bootstrap: [AppComponent]  
15})  
16 export class AppModule {}  
17
```

```
app.component.ts ×  
src > app > app.component.ts > ...  
1 import { Component } from '@angular/core';  
2  
3 @Component({  
4   selector: 'app-root',  
5   templateUrl: './app.component.html',  
6   styleUrls: ['./app.component.css']  
7 })  
8 export class AppComponent {  
9   title = 'first-app';  
10 }  
11
```

Angular Modules

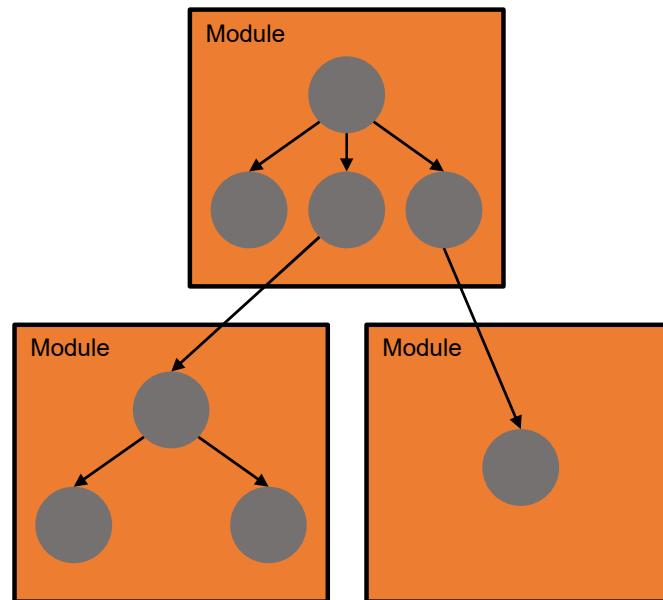

- Mechanism for organizing components in Angular
- Apps will have at least one main module (*AppModule* by convention)
- When Angular parses HTML and encounters a non-standard tag, it searches the component tree hierarchy for a matching selector

Angular Modules

- To be discoverable, an artifact needs to be registered with a module
- Angular apps support different types of modules and module hierarchies

@NgModule Decorator

- Modules in Angular are TypeScript classes marked with `@NgModule`
- Includes multiple properties used to link the hierarchy of application artifacts:
 - declarations
 - imports
 - exports
 - providers
 - bootstrap

@NgModule Decorator - declarations

- Lists components, directives and pipes registered with the module
- Can include artifacts that will be publicly available to module consumers
- Can also include artifacts that will be private to the module
- To be discoverable by runtime parsing, applicable artifacts need to be registered with a module

@NgModule Decorator - imports

- Lists other modules that contain declarations to be used by the module
- *CommonModule* will be listed automatically as import in a new module
- *CommonModule* contains all built-in directives and pipes
- Be on the lookout for circular references

@NgModule Decorator - exports

- Represents the public API for the module
- Lists artifacts from “declarations” to be made publicly available to other modules
- If not included here, artifact is internal to the module where registered

@NgModule Decorator - providers

- Lists services provided from the module
- However, services listed under “providers” in a module are available to any module in the app
- We’ll talk about different ways that service dependencies are managed in the section on Angular DI (Dependency Injection)

@NgModule Decorator - bootstrap

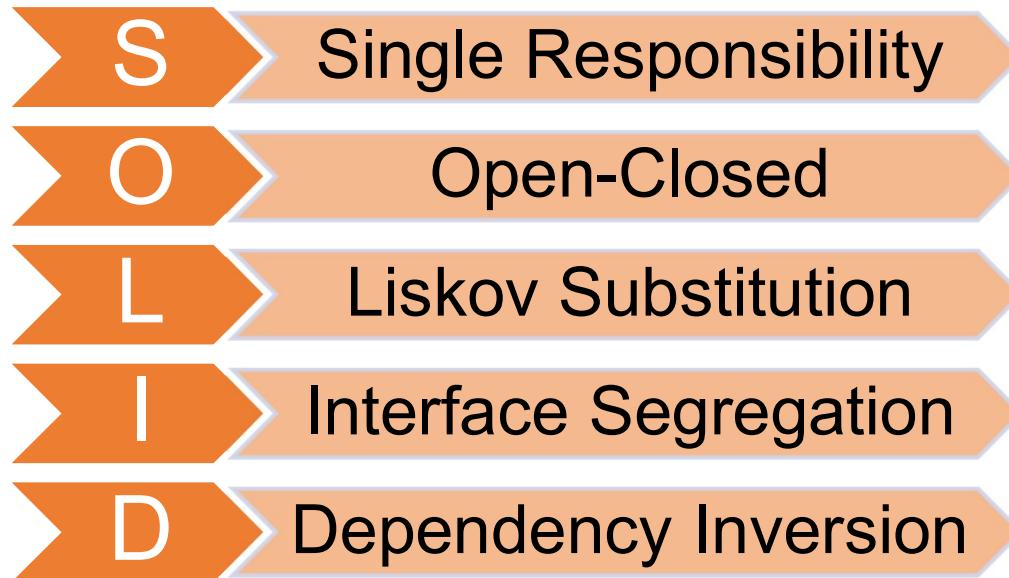

- Lists main component of app to be rendered on startup
- Set only once in the main module (usually *AppModule*)
- Usually called *AppComponent* (by convention)
- Likely set on initial project scaffolding with no need to change

Structuring an Angular App

- Follow SOLID principles for good application design
- Use modules to break a larger application into smaller pieces
- Associate Angular artifacts with the related module

Structuring an Angular App

- Ensure application functionality is coded in the right place
- Practice loose coupling and design for testability
- Multiple module types help us organize our Angular app

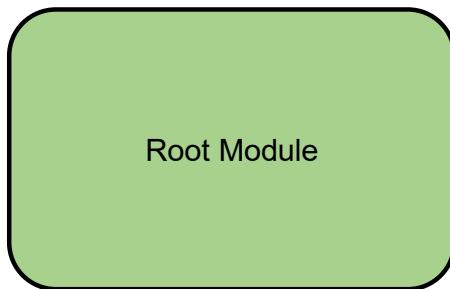

```

```

Root Module (Recap)

- Main module of an Angular app
- Named *AppModule* by convention
- Bootstrapped when the application starts
- Each Angular app only contains one with imports of other modules

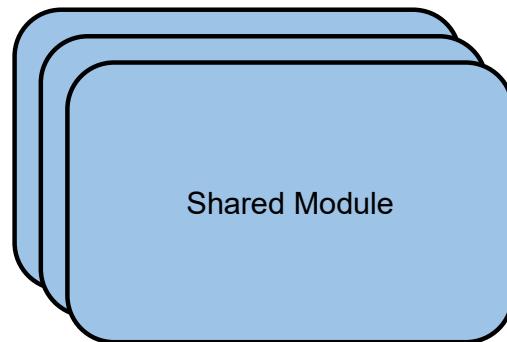

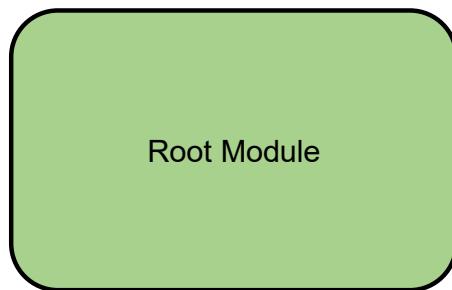

Shared Modules

- Modules that can be used for organizing cross-application artifacts
- Examples include layout & navigation components
- Can be used to house shared directives & pipes

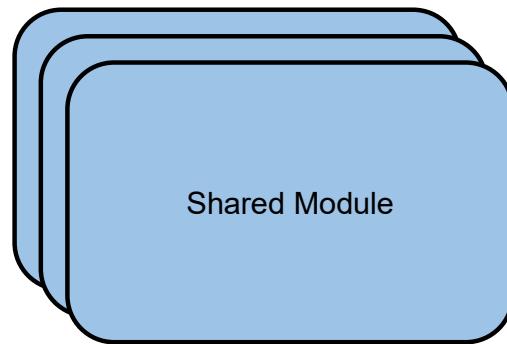

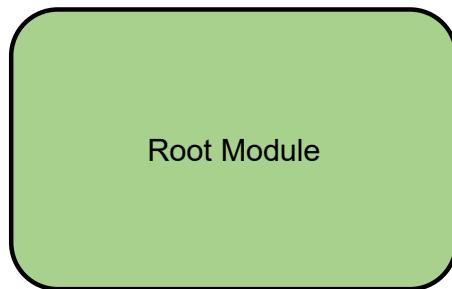

Shared Modules

- Can also be used to house shared services
- Alternatively, you can use folders to organize artifacts as well
- Key goals – clean organization of app structure and ability to find a specific artifact quickly

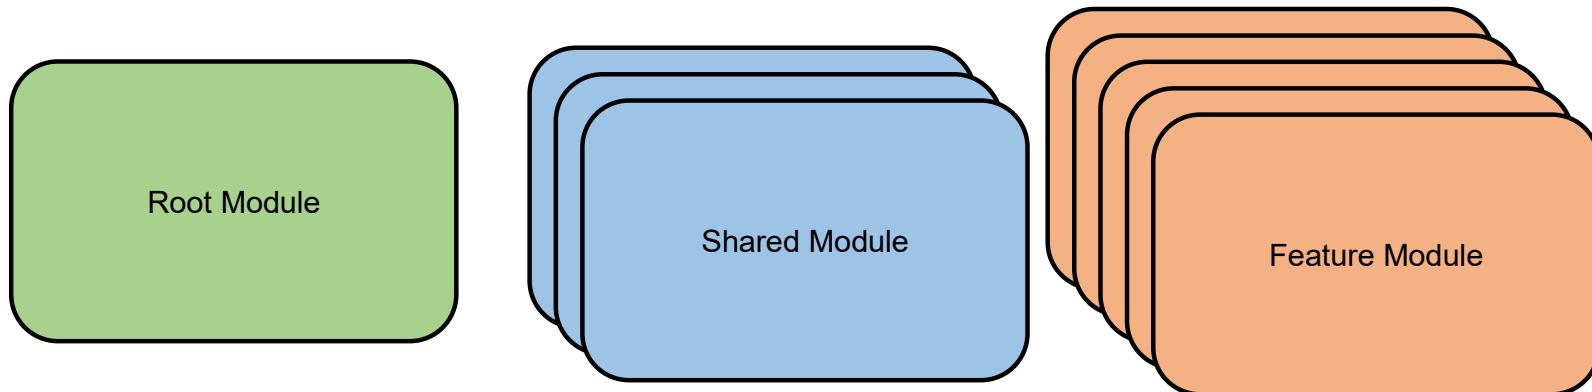

Feature Modules

- Modules dedicated to specific features in the app
- Examples include an ordering feature, a contact feature, a department feature, a widget feature, etc.
- As mentioned, enable you to divide a larger problem into smaller areas of development focus

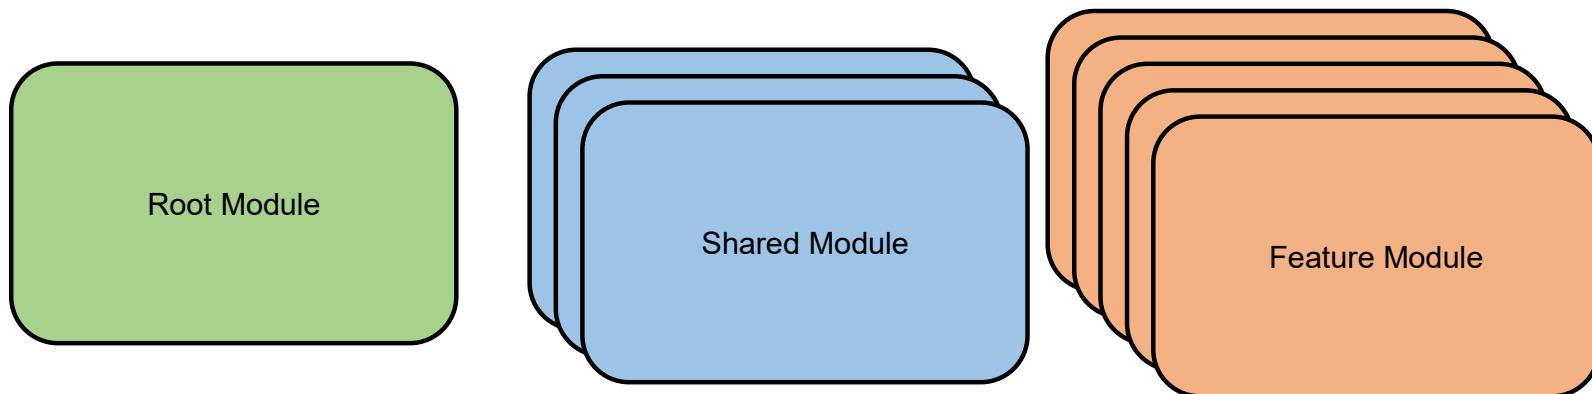

Feature Modules

- Supports parallel development efforts across a team
- Will usually not run standalone – intended for import from *AppModule* (or another module along the hierarchy)

Eagerly-Loaded vs. Lazy-Loaded

- Modules can be eagerly-loaded or lazy-loaded
- Eagerly-loaded modules get loaded when the app starts – declared in the “imports” property of another module
- Lazy-loaded modules are loaded on demand
- Not declared in an “imports” property

Eagerly-Loaded vs. Lazy-Loaded

- Instead, dynamically loaded (usually in response to a route change)
- Lazy-loaded modules can help reduce the size of the main bundle on build
- Separate, smaller bundles are created for each lazy-loaded module
- Useful for routes that are not expected to be accessed often (e.g., a “Contact Us” or “About Us” route)

Exercise 2

- In the app that you created in Exercise 1, create a new module called ordering
- Create a new order component (in ordering module)
- Export the order component from the ordering module
- Create a new order header component and new order detail component (both in ordering module)
- Add the order header component and order detail components to your order component
- Add the order component to the root component
- Confirm order header and order detail only available in order component's HTML
- Verify app using `ng serve --open`

Angular Components

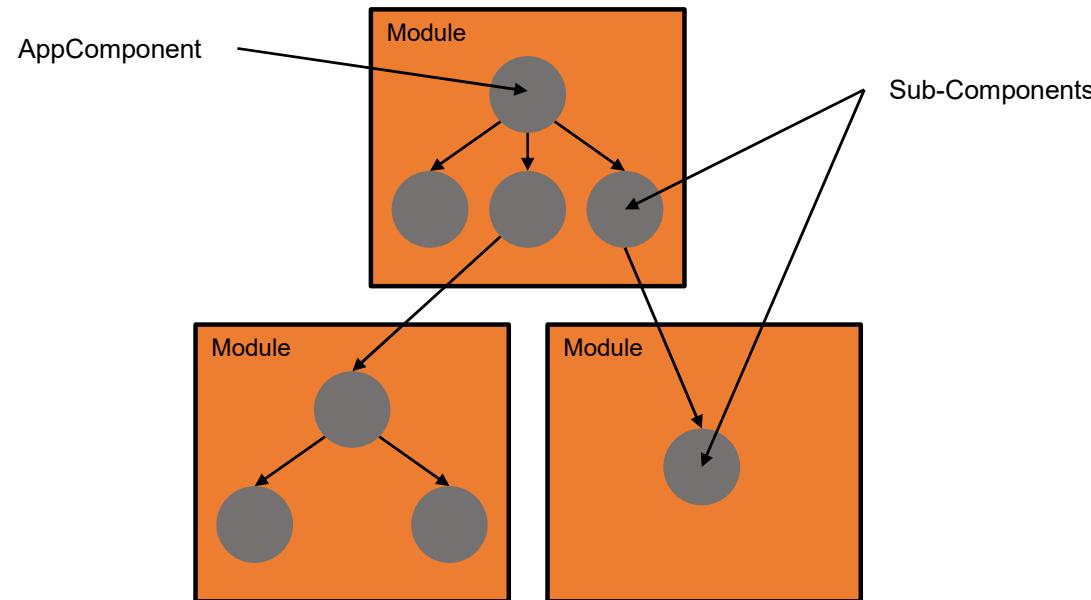

Angular Components

- The building blocks for our Angular application UI
- Control different pages or different parts of a page called “views”
- As previously mentioned, components in an Angular app compose a hierarchy (called the “component tree”)
- There are facilities for communicating data to and from a component

Angular Components

Creating Components

- To create a new component in Angular, we use *ng generate component <name>*
- Angular will append the word “Component” to the associated class name
- Angular will generate four files (by default):
 - <name>.component.html
 - <name>.component.css
 - <name>.component.ts
 - <name>.component.spec.ts

<name>.component.ts

- The TypeScript class for the component
- Where we place our view management and processing logic
- Houses properties used to populate data placeholders in the view
- Can include `@Input()` or `@Output()` decorators (for cross-component communication)

<name>.component.ts

- Uses `@Component()` decorator with a configuration object
- Includes a selector (the element name used to place the component)
- Includes a file reference (pointing to the HTML for the view) or inline HTML
- Includes a file reference (pointing to the CSS for the view) or inline styling

<name>.component.ts

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > Order HeaderComponent
1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';
2 import { DataService } from 'src/app/services/data.service';
3
4 @Component({
5   selector: 'app-order-header',
6   templateUrl: './order-header.component.html',
7   styleUrls: ['./order-header.component.css']
8 })
9 export class Order HeaderComponent implements OnInit {
10   status = 'Open';
11   @Input() orderNumber: string;
12   @Output() shipped = new EventEmitter<boolean>();
13
14   constructor(private dataService: DataService) { }
15
16   ngOnInit(): void {
17   }
18
19 }
20
21 }
```

<name>.component.ts

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > Order HeaderComponent
  1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';
  2 import { DataService } from 'src/app/services/data.service';
  3
  4 @Component({
  5   selector: 'app-order-header',
  6   template: `
  7     <div>
  8       <p>Order number is {{orderNumber}}</p>
  9       <p>Order status is {{status}}</p>
 10       <button (click)="shipped.emit(true)">Ship It</button>
 11     </div>
 12   `,
 13   styles: [
 14     `p:first-child {
 15       color: red;
 16     }`
 17   ]
 18 })
 19 export class Order HeaderComponent implements OnInit {
 20
 21   status = 'Open';
 22   @Input() orderNumber: string;
 23   @Output() shipped = new EventEmitter<boolean>();
 24
 25   constructor(private dataService: DataService) { }
 26
 27   ngOnInit(): void {
 28   }
 29
 30 }
 31
```

Creating Components

- By default, `ng generate component <name>` creates a folder for the component and component files in the path where run
- Alternatively, specify a target path during generation (e.g., `ng generate component ordering/orderDetail`)
- To use the component, it must be registered with a module

Creating Components

- If target path includes a module, the component will be registered with that module automatically
- Generating in the root folder of the app will register with *AppModule*
- Generating in a folder that does not include a module will register with *AppModule* (by default)

Creating Components

- *ng generate component <name> --module <module-name>* will target the named module for registration
- Angular converts camel-casing to kebab-casing (filenames and selectors) and Pascal-casing for class name
- Remember – include in “exports” of module to make component available outside of module

Displaying Component Data

- Interpolated expressions can be used to display component property values
- For example, `<p>Order number is {{orderNumber}}</p>`
- Alternatively, we can use property binding syntax (square brackets)

Displaying Component Data

- `<button (click)="ship.emit(true)" [innerText]="buttonText"></button>`
- “buttonText” in this example is a public property of the component (not a string literal)
- To set using a string literal, use single quotes within the double quotes -
`[innerText] = “Click Me!”`

Displaying Component Data

- We can also use component property binding with attributes of elements
- To do so, we use *attr.* syntax in the binding
- For example:

```
<button (click)="ship.emit(true)" [innerText]="buttonText" [attr.value] = "buttonText"></button>
```

One-Way Data Binding

- `<p>Order number is {{orderNumber}}</p>`
- `<button (click)="ship.emit(true)" [innerText]="buttonText"></button>`
- Creates a binding in the view – updates to the variables are automatically reflected in the display

One-Way Data Binding

- This binding is one-way though
- User input from the view (e.g., entering data in an `<input>` form field) is not persisted to the component variable

```
one-way.component.ts ×
src > app > one-way > one-way.component.ts > OneWayComponent > theData
1  import { Component, Input, OnInit } from '@angular/core';
2
3  @Component({
4    selector: 'app-one-way',
5    templateUrl: './one-way.component.html',
6    styleUrls: ['./one-way.component.css']
7  })
8  export class OneWayComponent implements OnInit {
9
10    @Input() theData: string;
11
12    constructor() { }
13
14    ngOnInit(): void {
15    }
16
17    showUpdatedData(): void {
18      console.log(this.theData);
19    }
20
21  }
22
```

one-way.component.html X

```
src > app > one-way > one-way.component.html > ...
1   <p>Data input is {{theData}}</p>
2   <div>
3     <label>Enter the Data:</label>
4     <input type="text" [value]="theData" />
5   </div>
6   <button (click)="showUpdatedData()">Update</button>
7
```

Update

Console

```
Angular is running in development mode. Call enableProdMode() to enable production mode.
[WDS] Live Reloading enabled.
Enter Data Here
```

Two-Way Data Binding

- Can make the binding two-way using template-driven forms and *ngModel*
- *ngModel* is a directive available upon import of *FormsModule*
- Add `[(ngModel)]="<var-name>"` to an input element to enable

```
one-way.component.html X
src > app > one-way > one-way.component.html > ...
1  <p>Data input is {{theData}}</p>
2  <div>
3  | <label>Enter the Data:</label>
4  | <input type="text" [(ngModel)]="theData" />
5  </div>
6  <button (click)="showUpdatedData()">Update</button>
7
```

Data input is Here Ya' Go

Template Reference Variables

- Named identifiers that can be added to elements in a component's template
- Prefixed by a hash symbol (#)
- Once assigned to an element, can use that name to reference the element in another part of the view
- Also, can grab a reference to the element in code using the name for programmatic interaction

The screenshot shows a code editor window with a dark theme. The file is named "one-way.component.html". The code contains several template reference variables, which are highlighted with red boxes:

```
1 <p>Data input is {{theData}}</p>
2 <p>Also {{theInput.value}}</p>
3 <div>
4   <label>Enter the Data:</label>
5   <input type="text" [(ngModel)]="theData" #theInput />
6 </div>
7 <button (click)="showUpdatedData()">Update</button>
```

Applying Styles to Component Template

- The template can use class binding or style binding for applying styles
- Class binding supports the `[class.<class-name>]=“<boolean expr>”` syntax
- For example, `...`
- If boolean expression evaluates to true, the `open` class will be applied to the element

Applying Styles to Component Template

- Class binding also supports alternate syntax
- For example, `<p [class] = "targetClasses">...</p>`
- `targetClasses` can be a property of the component and will be one of:
 - A space-delimited string of class names
 - An object with class names for keys and boolean expressions for values – a true value applies the class defined by the key

Applying Styles to Component Template

Component

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > OrderHeaderComponent > targetClasses
1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';
2 import { DataService } from 'src/app/services/data.service';
3
4 @Component({
5   selector: 'app-order-header',
6   templateUrl: './order-header.component.html',
7   styleUrls: ['./order-header.component.css']
8 })
9 export class OrderHeaderComponent implements OnInit {
10
11   status = 'Open';
12   @Input() orderNumber: string;
13   @Output() shipped = new EventEmitter<boolean>();
14   buttonText = 'Ship it NOW!';
15   targetClasses = 'open safe'; highlighted line
16
17   constructor(private dataService: DataService) { }
18
19   ngOnInit(): void {
20   }
21
22 }
23
```

Template

```
order-header.component.html X
src > app > ordering > order-header > order-header.component.html > ...
1 <div>
2   <p [class] = "targetClasses">Order Number is {{orderNumber}}</p>
3   <p>Order Status is {{status}}</p>
4   <button (click) = "shipped.emit(true)" [innerText] = "buttonText" [attr.value] = "buttonText"></button>
5 </div>
6
```

Applying Styles to Component Template

Component

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > Order HeaderComponent > targetClasses
1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';
2 import { DataService } from 'src/app/services/data.service';
3
4 @Component({
5   selector: 'app-order-header',
6   templateUrl: './order-header.component.html',
7   styleUrls: ['./order-header.component.css']
8 })
9 export class OrderHeaderComponent implements OnInit {
10
11   status = 'Open';
12   @Input() orderNumber: string;
13   @Output() shipped = new EventEmitter<boolean>();
14   buttonText = 'Ship it NOW!!';
15   targetClasses = {
16     open: this.status === 'Open',
17     safe: true
18   };
19
20   constructor(private dataService: DataService) { }
21
22   ngOnInit(): void {
23   }
24
25 }
26
```

Template

```
order-header.component.html X
src > app > ordering > order-header > order-header.component.html > ...
1 <div>
2   <p [class]="targetClasses">Order Number is {{orderNumber}}</p>
3   <p>Order Status is {{status}}</p>
4   <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>
5 </div>
6
```

Applying Styles to Component Template

- Style binding supports the `[style.<style-property>] = "<value>"` syntax
- For example, `<p [style.color] = "colorSelection">...</p>`
- Also, supports sub-levels of definition `[style.width.px] = "widthValue"`

Applying Styles to Component Template

- Like class binding, style binding supports alternate syntax as well
- For example, `<p [style] = "targetStyle">...</p>`
- `targetStyle` can be a property of the component and will be one of:
 - Style settings separated by a semicolon
 - An object with style properties for keys and style values for values

Applying Styles to Component Template

Component

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > Order HeaderComponent > targetStyles
1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';
2 import { DataService } from 'src/app/services/data.service';
3
4 @Component({
5   selector: 'app-order-header',
6   templateUrl: './order-header.component.html',
7   styleUrls: ['./order-header.component.css']
8 })
9 export class Order HeaderComponent implements OnInit {
10
11   status = 'Open';
12   @Input() orderNumber: string;
13   @Output() shipped = new EventEmitter<boolean>();
14   buttonText = 'Ship it NOW!!';
15   targetClasses = {
16     open: this.status === 'Open',
17     safe: true
18   };
19   targetStyles = 'color: darkred; width: 75px;';
20
21   constructor(private dataService: DataService) { }
22
23   ngOnInit(): void {
24   }
25
26 }
27
```

Template

```
order-header.component.html X
src > app > ordering > order-header > order-header.component.html > div > p
1 <div>
2   |   <p [class]="targetClasses">Order Number is {{orderNumber}}</p>
3   |   <p [style]="targetStyles">Order Status is {{status}}</p>
4   |   <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>
5   </div>
6
```

Applying Styles to Component Template

Component

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > Order HeaderComponent > targetStyles
1 import { Component, Event Emitter, Input, OnInit, Output } from '@angular/core';
2 import { DataService } from 'src/app/services/data.service';
3
4 @Component({
5   selector: 'app-order-header',
6   templateUrl: './order-header.component.html',
7   styleUrls: ['./order-header.component.css']
8 })
9 export class Order HeaderComponent implements OnInit {
10
11   status = 'Open';
12   @Input() orderNumber: string;
13   @Output() shipped = new Event Emitter<boolean>();
14   buttonText = 'Ship it NOW!';
15   targetClasses = {
16     open: this.status === 'Open',
17     safe: true
18   };
19   targetStyles = [
20     color: 'darkred',
21     width: '75px'
22 ]
23
24 constructor(private dataService: DataService) { }
25
26 ngOnInit(): void {
27 }
28
29 }
30
```

Template

```
order-header.component.html X
src > app > ordering > order-header > order-header.component.html > div > p
1 <div>
2   <p [class] = "targetClasses">Order Number is {{orderNumber}}</p>
3   <p [style] = "targetStyles">Order Status is {{status}}</p>
4   <button (click) = "shipped.emit(true)" [innerText] = "buttonText" [attr.value] = "buttonText"></button>
5 </div>
6
```

Sandboxing CSS Styles

- On browsers that support Shadow DOM, Angular will scope CSS styles local to the component (by default)
- Values assigned to the “styles” or “styleUrls” property of the `@Component()` decorator will be “sandboxed” to the component
- An additional property of the `@Component()` decorator (“encapsulation”) can be used to change

Sandboxing CSS Styles

- The “encapsulation” property can be set to one of the *ViewEncapsulation* enumeration values:
 - *Emulated* – the default; emulates Shadow DOM by preprocessing and renaming CSS in the rendered HTML
 - *ShadowDOM* – use the browser’s native Shadow DOM implementation (requires a browser that supports)
 - *None* – no view encapsulation; the component’s CSS gets added to global style
- *Emulated* (the default) is recommended

Exercise 3

- In the app that you modified in Exercise 2, create a new model class in the ordering folder for order header
- Create a new model class in the ordering folder for order details
- Add properties to the order header class for id, order number, description, total, and collection of order detail objects
- Add properties to the order detail class for id, order header id, product number, quantity, total
- In the order header component, create a new instance of order header, set default property values, and bind to order number and description property for display
- In the order detail component, create a new instance of order detail, set default property values, and bind to product number, quantity, and total for display
- In the order detail component, set up an input with two-way binding using ngModel for the quantity
- Confirm that changes to the input value are reflected real-time in the quantity display

Component Communication

Sharing Data

- Angular offers multiple options for sharing data between components
- Common use cases include:
 - Parent component to child component
 - Child component to parent component
 - Communication between sibling components

Parent to Child

- We can pass data into a component from a parent component host
- Called input binding and is accomplished using the `@Input()` decorator
- In its simplest form, `@Input() <prop-name>: <prop-type>;`
- For example, `@Input() orderNumber: string;`

Parent to Child

- The `@Input()` decorator accepts an optional parameter for alternate name
- Can also break out the associated property into a getter and a setter (for implementing additional logic on read vs. update)
- From the parent component, bind the child component property to a property of the parent (or a literal value)

Parent to Child

Component

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > ...
1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';
2 import { DataService } from 'src/app/services/data.service';
3
4 @Component({
5   selector: 'app-order-header',
6   templateUrl: './order-header.component.html',
7   styleUrls: ['./order-header.component.css']
8 })
9 export class OrderHeaderComponent implements OnInit {
10
11   status = 'Open';
12   @Input() orderNumber: string;
13   @Output() snipped = new EventEmitter<boolean>();
14   buttonText = 'Ship it NOW!!';
15   targetClasses = {
16     open: this.status === 'Open',
17     safe: true
18   };
19   targetStyles = 'color: darkred; width: 75px';
20
21   constructor(private dataService: DataService) { }
22
23   ngOnInit(): void {
24
25   }
26
27 }
```

Parent Component Template

```
app.component.html X
src > app > app.component.html > app-order-header
1 <app-order-header [orderNumber]="orderNumber" (shipped)="onShip($event)"></app-order-header>
2
```

or

```
app.component.html X
src > app > app.component.html > app-order-header
1 <app-order-header [orderNumber]="'ABC-123'" (shipped)="onShip($event)"></app-order-header>
2
```

Child to Parent

- We can push data from a child component to its host (or parent) component
- Called output binding and is accomplished using the `@Output()` decorator
- General syntax is `@Output() <event-name> = new EventEmitter();`
- For example, `@Output() shipped = new EventEmitter();`

- The *EventEmitter* class supports generics for targeting a specific data type
- By using, indicates the type of data expected for push on event occurrence
- From the child component, raise the event using *emit* (including any data to be communicated along with its occurrence)

Child to Parent

- From the parent component, bind the event to a handler method
- To process additional data accompanying the event, use `$event` as an argument in the handler
- The data can be utilized according to its defined type

Child to Parent

Child Component

```
order-header.component.ts X
src > app > ordering > order-header > order-header.component.ts > ...
1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';
2 import { DataService } from 'src/app/services/data.service';
3
4 @Component({
5   selector: 'app-order-header',
6   templateUrl: './order-header.component.html',
7   styleUrls: ['./order-header.component.css']
8 })
9 export class OrderHeaderComponent implements OnInit {
10
11   status = 'Open';
12   @Input() orderNumber: string;
13   @Output() shipped = new EventEmitter<boolean>();
14   buttonText = 'Ship it NOW!!';
15   targetClasses = {
16     open: this.status === 'Open',
17     safe: true
18   };
19   targetStyles = 'color: darkred; width: 75px;';
20
21   constructor(private dataService: DataService) { }
22
23   ngOnInit(): void {
24
25   }
26 }
27
```

Child Component Template

```
order-header.component.html X
src > app > ordering > order-header > order-header.component.html > div > p
1 <div>
2   <p [class]="targetClasses">Order Number is {{orderNumber}}</p>
3   <p [style]="#targetStyles">Order Status is {{status}}</p>
4   <button (click)="shipped.emit(true)" innerText="{{buttonText}}" [attr.value]={{buttonText}}></button>
5 </div>
6
```

Child to Parent

Parent Component

```
app.component.ts X
src > app > app.component.ts > ...
1 import { Component } from '@angular/core';
2
3 @Component({
4   selector: 'app-root',
5   templateUrl: './app.component.html',
6   styleUrls: ['./app.component.css']
7 })
8 export class AppComponent {
9
10  orderNumber = 'DEF-456';
11  title = 'first-app';
12
13  onShip(isShipped: boolean): void {
14    if (isShipped) { console.log('Shipped!'); }
15  }
16}
17
```

Parent Component Template

```
app.component.html X
src > app > app.component.html > app-order-header
1 <app-order-header [orderNumber]="orderNumber" (shipped)="onShip($event)"></app-order-header>
2
```

Between Siblings

- By siblings, we mean two or more child components hosted by same parent
- One option is a service for transferring data using *BehaviorSubject*
- Enables a publish/subscribe model for moving information between the components

Between Siblings

- Create a service and inject into the constructor of each sibling targeted for data sharing
- In the service, create and initialize a private *BehaviorSubject*
- Create a public variable with an observable “wrapper” around the *BehaviorSubject*
- Can then code a public API to enable consumers to push new data through the service (using the *next()* method of the observable)

Between Siblings

- One benefit of this approach is looser coupling between the components
- We'll discuss services, injection and observables further in later sections

```
A transfer.service.ts X
src > app > behavior-subject > A transfer.service.ts > ...
1 import { Injectable } from '@angular/core';
2 import { BehaviorSubject } from 'rxjs';
3
4 @Injectable({
5   providedIn: 'root'
6 })
7 export class TransferService {
8
9   private transferAgent = new BehaviorSubject<{ valueOne: string, valueTwo: string }>({ valueOne: '', valueTwo: '' });
10  transferAgent$ = this.transferAgent.asObservable();
11
12  constructor() { }
13
14  pushData(data: { valueOne: string, valueTwo: string }): void {
15    this.transferAgent.next(data);
16  }
17}
18
```

Between Siblings

- For the component receiving the data, subscribe to the observable
- For the component sending the data, call the service's API to initiate

Between Siblings

“Sending” Component

```
child2.component.ts ×  
src > app > behavior-subject > child2 > child2.component.ts > Child2Component > dataToTransfer  
1 import { Component, OnInit } from '@angular/core';  
2 import { TransferService } from '../transfer.service';  
3  
4 @Component({  
5   selector: 'app-child2',  
6   templateUrl: './child2.component.html',  
7   styleUrls: ['./child2.component.css']  
8 })  
9 export class Child2Component implements OnInit {  
10  
11   dataToTransfer = { valueOne: '', valueTwo: '' };  
12  
13   constructor(private transferService: TransferService) { }  
14  
15   ngOnInit(): void {  
16   }  
17  
18   sendData(): void {  
19     this.transferService.pushData(this.dataToTransfer);  
20   }  
21  
22 }  
23
```

“Sending” Component Template

```
child2.component.html ×  
src > app > behavior-subject > child2 > child2.component.html > ...  
1 <div>  
2   <input type="text" [(ngModel)]="dataToTransfer.valueOne" />  
3   <input type="text" [(ngModel)]="dataToTransfer.valueTwo" />  
4   <button (click)="sendData()">Send Data</button>  
5 </div>  
6
```

Between Siblings

“Receiving” Component

```
src > app > behavior-subject > child1 > child1.component.ts > ...
1 import { Component, OnDestroy, OnInit } from '@angular/core';
2 import { Subscription } from 'rxjs';
3 import { TransferService } from '../transfer.service';
4
5 @Component({
6   selector: 'app-child1',
7   templateUrl: './child1.component.html',
8   styleUrls: ['./child1.component.css']
9 })
10 export class Child1Component implements OnInit, OnDestroy {
11
12   private subscription: Subscription;
13   transferredData: { valueOne: string, valueTwo: string };
14
15   constructor(private transferService: TransferService) { }
16
17   ngOnInit(): void {
18     this.subscription = this.transferService.transferAgent$.subscribe(data => {
19       this.transferredData = { ...data };
20     });
21   }
22
23   ngOnDestroy(): void {
24     if (this.subscription) {
25       this.subscription.unsubscribe();
26     }
27   }
28
29 }
```

“Receiving” Component Template

```
src > app > behavior-subject > child1 > child1.component.html > ...
1 <div>
2   <p>First Value: {{ transferredData.valueOne }}</p>
3   <p>Second Value: {{ transferredData.valueTwo }}</p>
4 </div>
5
```

Component Communication

Demo

@ViewChild() Decorator

- Enables query selection against the DOM of a component's view
- Supports referencing by:
 - Component or directive type
 - Template reference variable (as a string)
 - Provider type (defined in child component tree of the component)
 - String token

@ViewChild() Decorator

- Accepts a parameter for target selector (based on type)
- Also accepts an optional parameter for a set of options:
 - *read* – Used to specify a different token for retrieval from the query results
 - *static* – Used to dictate whether query results should be resolved once before change detection (true) or after every change detection (false – the default)

@ViewChild() Decorator

- Using acquired reference, can update the queried element in code (set styles, text content, etc.)
- Can also call methods on the queried element as needed
- For initialization, `@ViewChild()` references are available in `ngAfterViewInit()` vs. `ngOnInit()`
- Query only has access to the component's template – cannot be utilized for referencing elements in its children or parent

@ContentChild() Decorator

- Enables query selection against the DOM of a component's projected content
- Using `<ng-content>` elements, can create placeholders to which content can be projected by the component's parent
- This projected content will not be accessible using `@ViewChild()`

@ContentChild() Decorator

- Accepts same parameter set used with `@ViewChild()`
- Accepts a parameter for target selector (based on type)
- Also accepts an optional parameter for a set of options:
 - `read` – Used to specify a different token for retrieval from the query results
 - `static` – Used to dictate whether query results should be resolved once before change detection (true) or after every change detection (false – the default)

@ContentChild() Decorator

- Similar capabilities as with `@ViewChild()`, but operates against projected content
- Using acquired reference, can update the queried element in code (set styles, text content, etc.)
- Can also call methods on the queried element as needed

@ContentChild() Decorator

- Target lifecycle hook for initialization should be `ngAfterContentInit()`
- As with `@ViewChild()`, query only has access to the component's content – not its children or parent

@ViewChild() and @ContentChild()

- When building dynamically-generated views from defined templates, programmatic access can be a powerful tool
- Also, enables additional capabilities at runtime vs. only interacting with statically-defined content
- Both support collection-based versions as well - `@ViewChildren()` and `@ContentChildren()`
- Return `QueryList` collections of matching elements

@ContentChild() and @ViewChild()

Demo

Exercise 4

- Start with the app that you modified in Exercise 3
- Add a new `@Input()` property for `orderHeader` in order header component
- Add a new `@Output()` event to order header component for `shipped`
- Add a new `@Input()` property for `orderDetail` in order detail component
- In the order component, create a new instance of order header and order detail, and set default property values
- Pass as `@Input()`'s from order component to the child components
- Verify that existing display and two-way binding continue to operate as expected
- Add a button to order header component that raises `shipped` event – emit the order header object as part of event payload (currently there will be no changes since component is view only but positions us for when we can modify)
- Handle event in order component and `console.log` order header details provided to the event in the payload

Component Lifecycle

Lifecycle Hooks

- Angular components follow a specific set of lifecycle stages
- Stages include various layers of initialization, change detection and teardown
- Optional “hooks” are provided in a set of interfaces that can be implemented in a component for custom logic

Lifecycle Hooks

- To utilize, we can implement one (or more) of the interfaces and code the associated method
- Helpful for implementing custom logic on occurrence of the lifecycle event
- For example, setting up a subscription to an observable on initialization and unsubscribing on component teardown

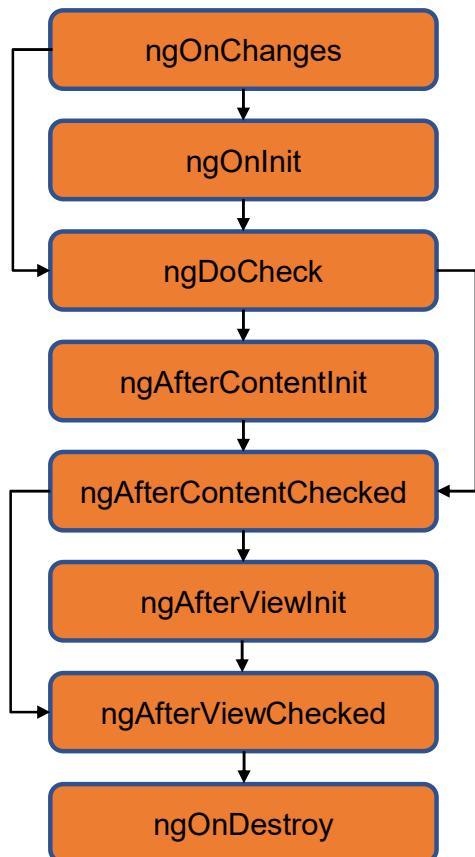

Lifecycle Hooks

- The interface and its associated lifecycle hook are named similarly - `<Interface Name>` and `ng<InterfaceName>()`
- For example, `OnInit` and `ngOnInit()`
- Technically, the interface does not need to be implemented – the presence of the method is enough
- However, best practice dictates that you should include both

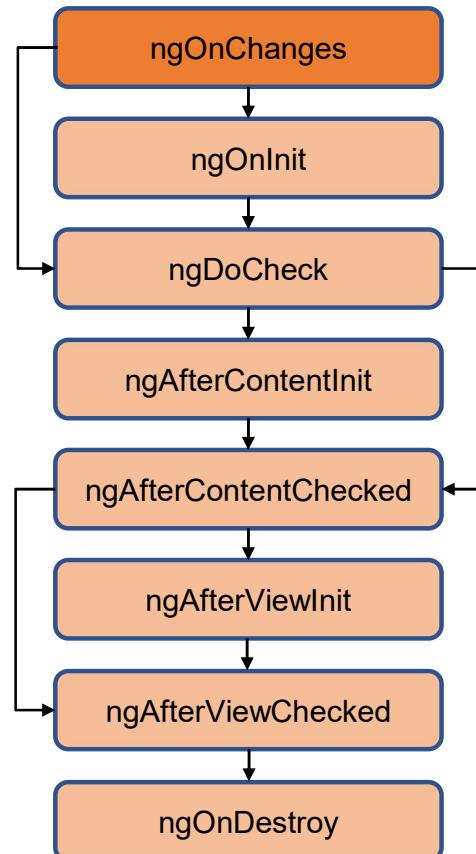

Lifecycle Hooks

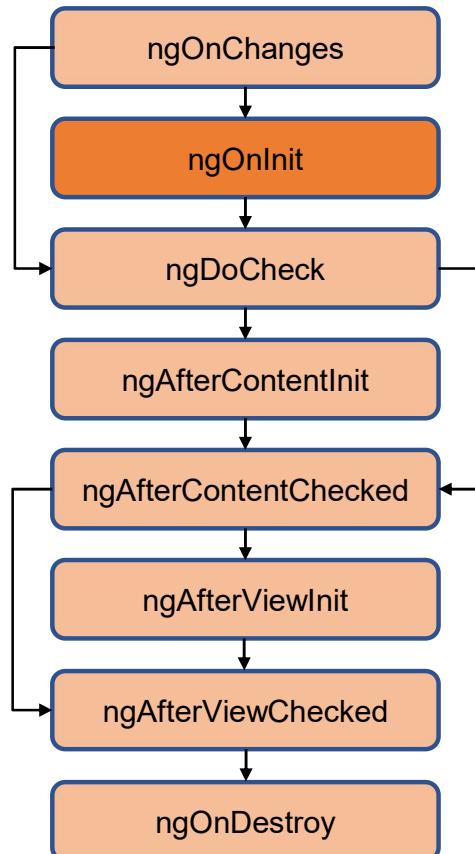

Lifecycle Hooks - ngOnChanges

- Called once before *ngOnInit* and then on every change to one or more data bound input properties
- Receives a *SimpleChanges* object containing a keyed entry for each changed property (by property name)
- Entry includes access to previous value and current value for property
- Also, includes an *isFirstChange()* method

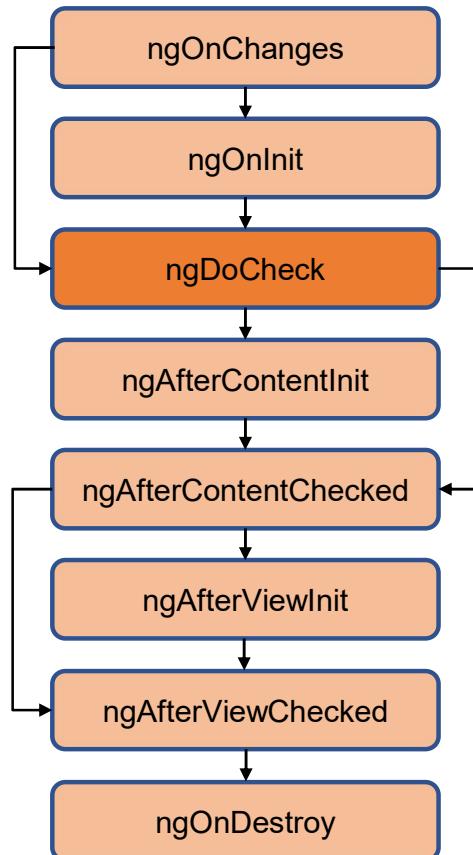

Lifecycle Hooks - ngOnInit

- Called once after first *ngOnChanges* call
- Captures initialization logic after set and first display of data bound properties
- Often used to pull initial data for component from service
- Enables initialization logic using data bound input property values (access not available in constructor)

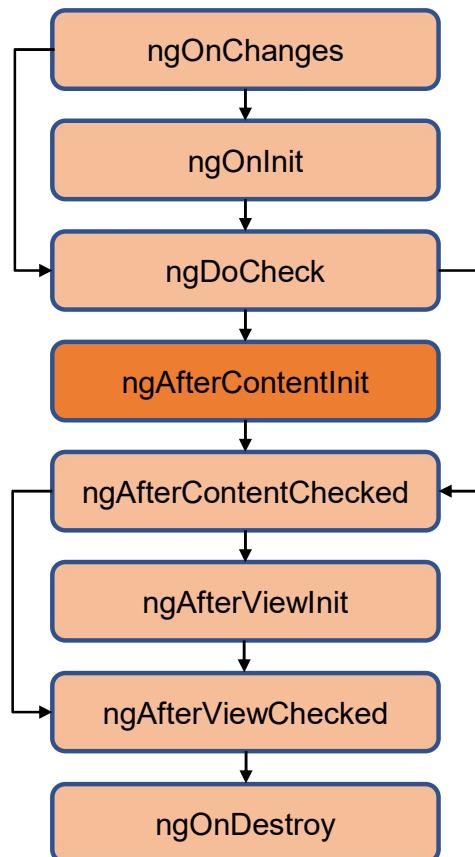

Lifecycle Hooks - ngDoCheck

- Called immediately after *ngOnInit* on component initialization
- Also, called immediately after *ngOnChanges* on every subsequent change detection run
- Enables customized change detection and response
- Best practice dictates that a component should not implement both *ngOnChanges* and *ngDoCheck*

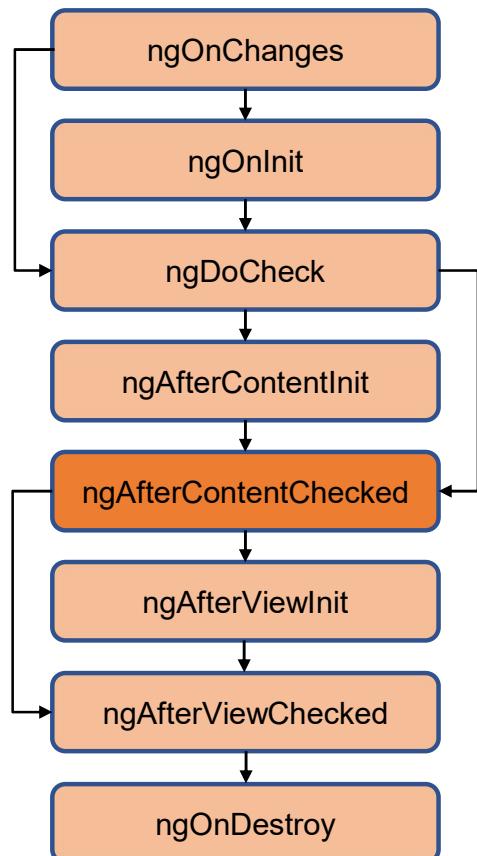

Lifecycle Hooks - ngAfterContentInit

- Called once after first *ngDoCheck()*
- Enables initialization logic against projected content
- Mentioned during *@ContentChild()* review

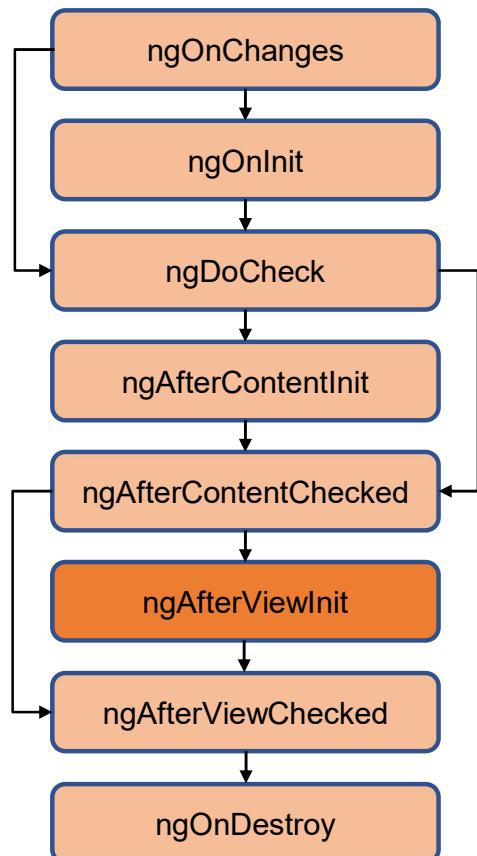

Lifecycle Hooks - ngAfterContentChecked

- Called after *ngAfterContentInit()*
- Also called after every subsequent *ngDoCheck()*
- Enables custom logic in response to projected content changes

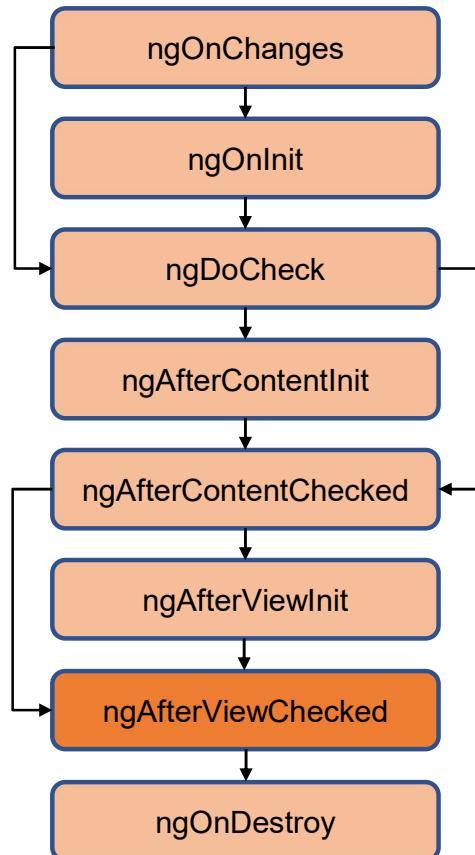

Lifecycle Hooks - ngAfterViewInit

- Called once after first *ngAfterContentChecked()*
- Enables initialization logic after a component's views and child views are setup and ready
- Mentioned during *@ViewChild()* review

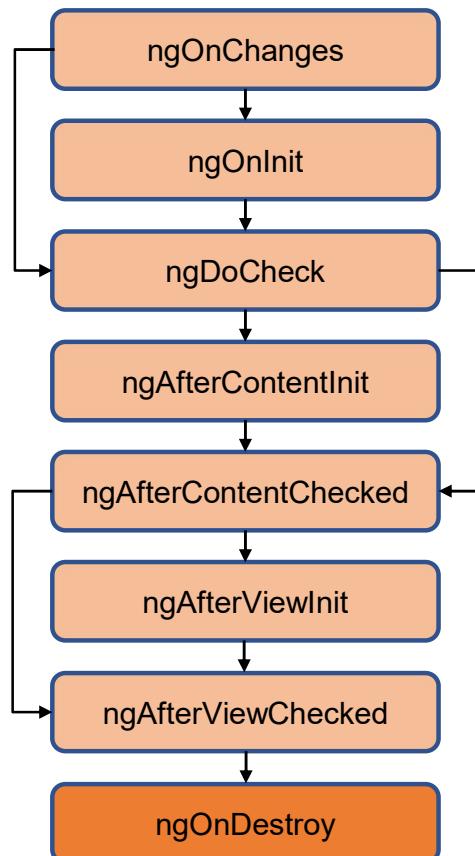

Lifecycle Hooks - ngAfterViewChecked

- Called after *ngAfterViewInit()*
- Also called after every subsequent *ngAfterContentChecked()*
- Enables custom logic in response to changes in the component's view and child views

Lifecycle Hooks - ngOnDestroy

- Called immediately before component is destroyed
- Used for cleanup logic – e.g., unsubscribing from observables, detaching event handlers, etc.
- Important for helping to prevent memory leaks

Component Change Detection

Change Detection Strategies

- Angular's change detection is critical to its ability to serve a dynamic app
- As changes occur (both user-generated and app-generated), application views update to reflect new content and values
- Non-deterministic process triggered in response to specific events

Change Detection Strategies

- Every component has a change detector associated to it
- To detect and apply changes, Angular compares the current value of a component property to the previous value
- If different, the component view is updated accordingly

Change Detection Strategies

- As discussed in the section on component lifecycle, there are hooks in which we can code custom logic to be executed on changes
- However, care should be taken as to amount and complexity of logic
- Otherwise, can result in a performance impact (given that changes likely occur many times)

ChangeDetectionStrategy

- Can also see performance impact with applications that include many component instances (e.g., large lists of items)
- With a component that includes object references, change detection will trigger on updates to the object's properties (or sub-properties)
- Depending on the complexity of the component tree, may need to manage differently to optimize user experience

ChangeDetectionStrategy

- For those cases, a different change detection strategy can be set for the component
- The `@Component()` decorator's object parameter includes an optional `changeDetection` designation
- Type of this property is `ChangeDetectionStrategy` (an enum)

ChangeDetectionStrategy

- *ChangeDetectionStrategy* supports two possible values:
 - *Default* (which is the default strategy)
 - *OnPush*
- When set to *Default* (or left unset), Angular will leverage standard change detection

ChangeDetectionStrategy

- When set to *OnPush*, change detection is triggered only when references for `@Input()` properties change
- This can improve performance but requires some modifications to reflect change in our views
- One option is to use the spread operator (...) for managing updates to objects and arrays in an immutable manner

Spread Operator (...)

- For arrays, instead of calling `push()` to add a new element, create a new array from the existing one

```
this.values = [...this.values, 'Added Value'];
```

- Using this approach, the reference will be updated (triggering `OnPush` change detection)

Spread Operator (...)

- For objects, instead of modifying properties of an existing instance, create a new instance

```
this.objectRef = { ...this.objectRef, prop1: 'update' };
```

-or-

```
this.objectRef = { ...this.objectRef };
this.objectRef.prop1 = 'Update';
```

- As with arrays, the reference will be updated (triggering *OnPush* change detection)

ChangeDetectorRef

- Alternatively, can use *ChangeDetectorRef* to manage change detection
- Includes the following methods:
 - *markForCheck()* – marks the view (and its ancestors up to root) as changed for recheck (at some point in future)
 - *detach()* – detaches the view from change-detection
 - *detectChanges()* – explicitly triggers change detection for the view and its children
 - *reattach()* – reattaches a detached view

Exercise 5

- In a new Angular app, create a parent component and a child component
- In the parent, include public properties for an array and an object (properties of your choosing)
- Initialize the properties in the parent component (you choose the values)
- In the child, include input bindings for the array and the object
- In the child view, display each array element as a within a
- In the child view, use a <p> element to display the object properties in JSON format
- In the parent, include an instance of the child and pass the properties as inputs
- Create a button in the parent component that adds a new element to the array
- Create a button in the parent component that modifies one or more properties of the object
- Test using ng serve --open to confirm that changes are reflected when the button is pushed in the parent
- Change the change detection strategy for the child component to “OnPush”
- See what happens when attempting to press the button in the parent (for updates)
- Can you make the necessary fixes to approach to pick up changes (leaving OnPush in place)?

Angular Directives

Angular Directives

- Custom HTML attribute applied to another HTML element
- Used when we want to customize HTML layout or how an element behaves or looks
- Angular provides a set of built-in directives
- However, we can create our own custom directives as well

Types of Directives

- There are three types of directives:
 - Components – Directives with a template
 - Structural Directives – Used to add or remove elements from the DOM
 - Attribute Directives – Used to modify appearance or add custom behavior to a DOM element

Built-In Directives

- Include the following:
 - *ngIf* (structural)
 - *ngFor* (structural)
 - *ngSwitch* (structural)
 - *ngClass* and *ngStyle* (attribute)
- Let's take a closer look at each one

- Used to conditionally add or remove an HTML element in the DOM
- Uses a boolean expression to manage
- If expression evaluates to true, element is inserted into the DOM
- If false, the element is removed
- Does not simply manage visibility of element but actual presence in tree

ngIf

Component

```
order-header.component.ts ×  
src > app > ordering > order-header > order-header.component.ts > ...  
1 import { Component, EventEmitter, Input, OnInit, Output } from '@angular/core';  
2 import { DataService } from 'src/app/services/data.service';  
3  
4 @Component({  
5   selector: 'app-order-header',  
6   templateUrl: './order-header.component.html',  
7   styleUrls: ['./order-header.component.css']  
8 })  
9 export class OrderHeaderComponent implements OnInit {  
10  
11   status = 'Open';  
12   @Input() orderNumber: string;  
13   @Output() shipped = new EventEmitter<boolean>();  
14   buttonText = 'Ship it NOW!!';  
15   targetClasses = {  
16     open: this.status === 'Open',  
17     safe: true  
18   };  
19   targetStyles = 'color: darkred; width: 75px;';  
20  
21   constructor(private dataService: DataService) { }  
22  
23   ngOnInit(): void {  
24   }  
25  
26 }  
27
```

Component Template

```
order-header.component.html ×  
src > app > ordering > order-header > order-header.component.html > div > p  
1 <div>  
2   <p [class]="targetClasses">Order Number is {{orderNumber}}</p>  
3   <p *ngIf="status === 'Open'" [style]="targetStyles">Order Status is {{status}}</p>  
4   <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>  
5 </div>  
6
```

DOM When Status is “Open”

```
...<!DOCTYPE html> == $0
<html lang="en">
  <head>...</head>
  <body>
    <app-root _ngcontent-dbl-c12 ng-version="11.0.5">
      <app-order-header _ngcontent-dbl-c12 _ngcontent-dbl-c11 ng-reflect-order-number="DEF-456">
        <div _ngcontent-dbl-c11>
          <p _ngcontent-dbl-c11 class="open safe">Order Number is DEF-456</p>
          <p _ngcontent-dbl-c11 style="color: darkred; width: 75px;">Order Status is Open</p>
          <!--bindings={-->
            <ng-reflect-ng-if: "true" -->
          <!--bindings={-->
            <button _ngcontent-dbl-c11 value="Ship it NOW!!">Ship it NOW!!</button>
          </div>
        </app-order-header>
      </app-root>
      <script src="runtime.js" defer></script>
      <script src="polyfills.js" defer></script>
      <script src="vendor.js" defer></script>
      <script src="main.js" defer></script>
    </body>
  </html>
```

DOM When Status is “Closed”

```
...<!DOCTYPE html> == $0
<html lang="en">
  <head>...</head>
  <body>
    <app-root _ngcontent-hcc-c12 ng-version="11.0.5">
      <app-order-header _ngcontent-hcc-c12 _ngcontent-hcc-c11 ng-reflect-order-number="DEF-456">
        <div _ngcontent-hcc-c11>
          <p _ngcontent-hcc-c11 class="safe">Order Number is DEF-456</p>
          <!--bindings={-->
            <ng-reflect-ng-if: "false" -->
          <!--bindings={-->
            <button _ngcontent-hcc-c11 value="Ship it NOW!!">Ship it NOW!!</button>
          </div>
        </app-order-header>
      </app-root>
      <script src="runtime.js" defer></script>
      <script src="polyfills.js" defer></script>
      <script src="vendor.js" defer></script>
      <script src="main.js" defer></script>
    </body>
  </html>
```

ngIf With else

- If an alternate element is to be displayed instead, we have a couple of options:
 - Add another `*ngIf` using an opposite boolean expression
 - Use an `else` with an `<ng-template>` element and a template reference variable

```
order-header.component.html x
src > app > ordering > order-header > order-header.component.html > ...
1   <div>
2   |   <p [class]="targetClasses">Order Number is {{orderNumber}}</p>
3   |   <p *ngIf="status === 'Open'; else closedOrder" [style]="targetStyles">Order Status is {{status}}</p>
4   |   <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>
5   </div>
6
7   <ng-template #closedOrder>
8   |   <p>No open order found</p>
9   </ng-template>
10
```

ngIf Using <ng-template>

- In fact, an *<ng-template>* can be used for both the **ngIf* and the *else*
- Additional **ngIf* statements can be nested within the *<ng-template>* definitions for testing more conditions (if-elseif)

```
order-header.component.html ×
src > app > ordering > order-header > order-header.component.html > div > ng-template
1  <div>
2  |   <p [class]="targetClasses">Order Number is {{orderNumber}}</p>
3  |   <ng-template *ngIf="status === 'Open'; then openOrder else closedOrder"></ng-template>
4  |   <button (click)="shipped.emit(true)" [innerHTML]= buttonText [attr.value]= "buttonText"></button>
5  </div>
6
7  <app-order-detail *ngFor="let orderDetail of orderDetails" [detail]="orderDetail"></app-order-detail>
8
9  <ng-template #openOrder>
10 |   <p [style]= "targetStyles">Order Status is {{status}}</p>
11 </ng-template>
12
13 <ng-template #closedOrder>
14 |   <p>No open order found</p>
15 </ng-template>
16
```

ngFor

- Used to iterate over a collection of items and render a template for each
- Observes changes in the underlying collection and updates rendered templates as items are added, removed or reordered

```
order-header.component.html ×  
src > app > ordering > order-header > order-header.component.html > ng-template  
1   <div>  
2     <p [class]="targetClasses">Order Number is {{orderNumber}}</p>  
3     <p *ngIf="status === 'Open'; else closedOrder" [style]="targetStyles">Order Status is {{status}}</p>  
4     <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>  
5   </div>  
6  
7   <app-order-detail *ngFor="let orderDetail of orderDetails" [detail]="orderDetail"></app-order-detail>  
8  
9   <ng-template #closedOrder>  
10    <p>No open order found</p>  
11  </ng-template>  
12
```

Ship it NOW!!
DDA1334 at a count of 25
DAE5543 at a count of 100
WQA4590 at a count of 2
TYR0003 at a count of 45

ngFor – Additional Properties

- *ngFor supports creation of a local reference variable for each item in the collection
- This variable can be used in the template as well
- Format is `*ngFor="let item of items; <property> as <var-name>"`
- Property can be:
 - `index` – 0-based index of item in collection
 - `first/last` – boolean indicating whether item is first or last item
 - `even/odd` – boolean indicating whether `index` of item is even or odd

ngFor – Additional Properties

- Multiple can be chained together separated by semi-colons

The screenshot shows a code editor window with a dark theme. The file is named 'simple-list.component.html'. The code is as follows:

```
src > app > simple-list > simple-list.component.html > ...
1   <ul>
2     <li *ngFor="let item of items; index as indexVal; odd as isIndexOdd" [class.highlight]="isIndexOdd">
3       {{indexVal + 1}}. {{item}}
4     </li>
5   </ul>
6 
```

A red box highlights the line of code containing the ngFor directive and its additional properties: 'index as indexVal; odd as isIndexOdd'.

- 1. Widgets
- 2. Hammers
- 3. Screwdrivers
- 4. Televisions
- 5. PS5 Consoles

ngFor – trackBy

- By default, *ngFor uses object identity to track items in a collection
- Assume a method that loads a collection of objects
- Can use *ngFor to display that collection
- By default, when the collection is reset (even with same data), *ngFor is re-rendered in whole

ngFor – trackBy

- Using trackBy, can specify property of items in the collection to be used to determine need for re-render
- Still supports robust change detection for item property changes but manages collection render more performantly

```
order-list.component.ts ×
src > app > ordering > order-list > order-list.component.ts > OrderListComponent > loadAll
1 import { Component, OnInit } from '@angular/core';
2 import { OrderService } from 'src/app/services/order.service';
3 import { OrderHeader } from '../order-header.model';
4
5 @Component({
6   selector: 'app-order-list',
7   templateUrl: './order-list.component.html',
8   styleUrls: ['./order-list.component.css']
9 })
10 export class OrderListComponent implements OnInit {
11
12   orders: Array<OrderHeader>;
13
14   constructor(private orderService: OrderService) {}
15
16   ngOnInit(): void {
17   }
18
19   loadAll(): void {
20     this.orders = this.orderService.getOrders();
21   }
22
23   trackOrderId(index: number, order: OrderHeader): number {
24     return order.id;
25   }
26
27 }
28
```

```
order-list.component.html ×
src > app > ordering > order-list > order-list.component.html > ...
1 <button (click)="loadAll()">Get All Orders</button>
2 <table>
3   <tr>
4     <th>Order Number</th>
5     <th>Description</th>
6     <th>Total</th>
7   </tr>
8   <tr *ngFor="let order of orders; trackBy: trackOrderId">
9     <td [attr.data-id]="order.id">{{order.orderNumber}}</td>
10    <td>{{order.description}}</td>
11    <td>{{order.total | currency }}</td>
12  </tr>
13 </table>
14
```

ngSwitch

- Used to switch between templates based on the value of a variable or expression
- Akin to a switch-case statement in code
- `[ngSwitch]` is used to specify the variable or expression

ngSwitch

- `*ngSwitchCase` is used to define the template to be added if its value matches
- `*ngSwitchDefault` is used to define a default template if none of the values match
- Unlike switch-case, there is no fallthrough or break

ngSwitch

```
order-header.component.html X
src > app > ordering > order-header > order-header.component.html > div
  1  <div>
  2    <p [class]="targetClasses">Order Number is {{orderNumber}}</p>
  3    <ng-container [ngSwitch]="status">
  4      <p *ngSwitchCase="'Open'" [style]="targetStyles">Order Status is {{status}}</p>
  5      <p *ngSwitchCase="'Closed'">No open order found</p>
  6      <p *ngSwitchDefault>Order status is unknown</p>
  7    </ng-container>
  8    <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>
  9  </div>
10
11 <app-order-detail *ngFor="let orderDetail of orderDetails" [detail]="orderDetail"></app-order-detail>
12
```

ngClass and ngStyle

- *ngClass* is used to add or remove CSS classes on an HTML element
- *ngStyle* is used update styles on an HTML element

- *ngClass* accepts the following types of expressions:
 - Space-delimited string of class names to be applied
 - An array of string class names to be applied
 - An object with class names for keys and boolean expressions for values – a true value applies the class defined by the key
- In the object expression, multiple space-delimited class values can be managed by the same boolean expression

ngClass

```
5 order-header.component.html X
src > app > ordering > order-header > 5 order-header.component.html > ...
1  <div>
2  |  <p [ngClass]="{'open safe': status === 'Open'}">Order Number is {{orderNumber}}</p>
3  |  <ng-container [ngSwitch]="status">
4  |  |  <p *ngSwitchCase="'Open'" [style]="targetStyles">Order Status is {{status}}</p>
5  |  |  <p *ngSwitchCase="'Closed'">No open order found</p>
6  |  |  <p *ngSwitchDefault>Order status is unknown</p>
7  |  </ng-container>
8  |  <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>
9  </div>
10
11 <app-order-detail *ngFor="let orderDetail of orderDetails" [detail]="orderDetail"></app-order-detail>
12
```

- *ngStyle* accepts one or more style identifiers with corresponding expressions
- If the expression evaluates to a non-null value, the style is applied
- Otherwise, the style is removed

- Where applicable, supports an optional unit suffix
- Also supports object expressions containing a set of key-value pairs

```
order-header.component.html X
src > app > ordering > order-header > order-header.component.html > ...
1  <div>
2    <p [ngClass]="{{'open safe': status === 'Open'}}>Order Number is {{orderNumber}}</p>
3    <ng-container [ngSwitch]="status">
4      <p *ngSwitchCase="'Open'" [ngStyle]="{'background-color': colorValue, 'width.%': widthValue}">Order Status is {{status}}</p>
5      <p *ngSwitchCase="'Closed'">No open order found</p>
6      <p *ngSwitchDefault>Order status is unknown</p>
7    </ng-container>
8    <button (click)="shipped.emit(true)" [innerText]="buttonText" [attr.value]="buttonText"></button>
9  </div>
10
11 <app-order-detail *ngFor="let orderDetail of orderDetails" [detail]="orderDetail"></app-order-detail>
12
```

Creating Custom Directives

- To create a custom directive, we use `ng generate directive <name>`
- Angular creates a TypeScript file for the directive called `<name>.directive.ts`
- Be aware – directive will be created in the folder where `ng generate` is executed
- It will be registered with a module local to the folder (or `AppModule` if none exists there)

@Directive() Decorator

- Directive is defined by TypeScript class decorated with `@Directive()`
- Accepts an object parameter that includes a property called `selector`
- Property is required and represents named placeholder applied to target host

Data Bindings in Directives

- As with components, `@Input()` properties can be applied to directives
- Creates input bindings for the directive
- Defined input bindings are specified on the host where directive is applied
- For example, `<p myDirective [inputVal] = "value">...</p>`

Data Bindings in Directives

- Can also use the directive as an input binding as well (subject to some rules)
- Requires an `@Input()` property with same name as directive selector
- Attribute directives support additional inputs in the standard way

```
1 import { Directive, HostBinding, HostListener, Input } from '@angular/core';
2
3 @Directive({
4   selector: '[appNumbersOnly]'
5 })
6 export class NumbersOnlyDirective {
7
8   @Input('appNumbersOnly') numbersOnly: boolean;
9   @Input() validClass: string;
10  @Input() invalidClass: string;
11}
```

```
1 <input [appNumbersOnly]="true" [validClass]="'valid'" [invalidClass]="'invalid'" />
2
```

Data Bindings in Directives

- Structural directives require additional input names to be prefixed with the directive selector
- Host syntax is different as well

```
1 import { Directive, Input, TemplateRef, ViewContainerRef, OnInit } from '@angular/core';
2
3 @Directive({
4   selector: '[appViewManager]'
5 })
6 export class ViewManagerDirective implements OnInit {
7
8   @Input() appViewManager: string[];
9   @Input('appViewManagerSecondaryRoles') secondaryRoles: string[] = [];
10
11  private currentRole = 'supervisor';
```

```
1 <input [appNumbersOnly]='true' [validClass]="'valid'" [invalidClass]="'invalid'" />
2 <div *appViewManager='["supervisor", "plant manager"]; secondaryRoles: ["admin"]>
3   <p>Super-secret display area!!</p>
4 </div>
5
```

Data Bindings in Directives

- Means that structural directives require an input property with name matching selector if additional inputs are required
- Attribute directives do not
- Additionally, not required to have any input bindings if intent is to use presence of directive only

Bindings Directive Details to Host

- `@HostBinding()` decorator can be used to bind a directive value to property of host element
- `@HostListener()` decorator can be used to bind to an event of host element
- Enables implementation of custom logic in directive tied to details of the host
- For example, binding to the `class` attribute for programmatically updating styles on the host

Exercise 6

- Start with the ordering app that you modified in exercise 4
- Change the description in order header component to be an input (instead of display only)
- Create a new custom directive for preventing “bad words” – use a safe collection like ['stupid', 'bad', 'dumb'] 😊
- Apply the directive to the description input in the header component – if user attempts to enter one of the “bad words”, remove it automatically from the input as they exit the control
- Create another customer directive for managing display of an element or component based on user role
- Use a constant set of role names that are authorized (e.g., ['admin', 'supervisor'])
- Hard-code current user's role name (not how we would really handle)
- Apply the directive to the order detail component and prevent display if user not in set of authorized roles
- If time permits, add an input binding to the “bad words” directive to pass in a class to use for styling when “bad word” is attempted
- If time permits, add an input binding to the user role directive that accepts a collection of additional/secondary roles and user's current role

Angular Pipes

Angular Pipes

- Pipes allow the filtering and transformation of data at the view level
- The applied pipe does not persist any changes to the underlying data
- General format is `<expression> | <pipe name>`
- Also support chaining for additional view transformation (i.e., `<expression> | <pipe1> | <pipe2>`)

Built-In Pipes

- Several built-in pipes are available for use:
 - *uppercase/lowercase* – transforms string to designated casing
 - *percent* – formats a number as a percentage
 - *currency* – formats a number as local currency; can override with different currency code
 - *slice* – retrieves a subset of elements from an array; accepts starting index and optional ending index
 - *date* – formats expression as a date; accepts an optional format string
 - *json* – outputs an object in JSON format; useful for debugging purposes

Built-In Pipes

```
1 <p>{{'this is some text' | uppercase }}</p>
2 <p>{{'THIS IS SOME OTHER TEXT' | lowercase}}</p>
3 <p>{{0.23239543 | percent:'0.2'}}</p>
4 <p>{{945.32344 | currency:'EUR'}}</p>
5 <p>{{[1, 2, 3, 4] | slice:1:3}}</p>
6 <p>{{[1, 2, 3, 4] | slice:1}}</p>
7 <p>{{currentDate | date: 'fullDate'}}</p>
8 <p>{{currentDate | date: 'yyyy-MM-dd'}}</p>
9 <p>{{obj | json}}</p>
10
```

{ "prop1": "One", "prop2": "Two", "prop3": "Three", "prop4": "Four" }

Creating Custom Pipes

- To create a custom pipe, we use `ng generate pipe <name>`
- Angular creates a TypeScript file for the pipe called `<name>.pipe.ts`
- Be aware – pipe will be created in the folder where `ng generate` is executed
- It will be registered with a module local to the folder (or `AppModule` if none exists there)

@Pipe() Decorator

- Pipe is defined by TypeScript class decorated with `@Pipe()`
- Accepts an object parameter that includes a property called `name`
- Property is required and represents name used with `|`
- The pipe class will implement the `PipeTransform` interface

PipeTransform

- Includes a single method called *transform* that will contain pipe's transformation logic
- Format of initial scaffolded method will look like this:

```
transform(value: unknown, ...args: unknown[]): unknown {  
  return null;  
}
```

- We modify input types, output type and implement pipe logic, returning results of transformation

- *value* parameter will be the value to which the pipe is being applied
- Specific parameters can be added to the pipe signature (if required)
- When applying the pipe, parameters will be separated with a colon (:)

transform(value: Person[], primarySort: string, secondarySort?: string) : Person[]

*<li *ngFor="let person of people | sorter:'lastName'">...*
-or-

*<li *ngFor="let person of people | sorter:'lastName':'firstName'">...*

Angular Pipes

- By default, a custom pipe is re-executed only when the reference of the value changes
- These are known as “pure” pipes (the default)
- If items added to array or properties of object change, use immutable data management techniques to modify
- Resets reference (causing pipe to re-execute)

Exercise 7

- Start with the ordering app that you modified in exercise 6
- Add a “customer name” attribute to the order header model
- Create a custom “order sorter” pipe that will sort order headers by customer name then by total
- Change your order header component to work with a collection of order headers instead of a single
- You don’t need to make any changes to the order detail component for this exercise
- Create a collection of order header objects in the order header component (or hard code in a service and use that to retrieve)
- Use an *ngFor directive to build a table-like structure for the order header collection in the order header component (you can remove or comment out the input binding/output binding)
- Apply the “order sorter” to order header table display to order as described
- Use the currency built-in pipe for display of total
- If time permits, attempt to also implement an additional argument on the pipe for ascending vs. descending order for total; by default, sort total ascending – enable user to toggle the sort to order by descending (NOTE: Customer name will always be ascending – the toggle is for total only)

Exercise 7

Orders

Order Number	Description	Customer Name	Total
...	\$X.XX
...	\$X.XX

Toggle

Order Detail

Static Order Detail View

Initially sorts customer name asc, then total asc.
On toggle, sorts customer name asc, then total desc

Angular Routing

Angular Routing

- Facilitates navigation between different components (e.g., routing from list view to detail view)
- Defines a set of paths and the component that should be rendered for each
- When user hits that path in the browser, app will render the component

Angular Routing

- Enables a more dynamic navigation experience
- Instead of static component tags in our HTML, we use a generic routing placeholder
- Supports definition of a “wildcard path” as a catch-all if none of the route paths match
- Also enables designation of route-based parameters

Adding Angular Routing

- When creating a new app using `ng new`, the Angular CLI will ask if routing should be enabled
- Creates the necessary scaffolding for routing on app creation
- However, can also add routing to an existing app not scaffolded for it

Adding Angular Routing

- Check “package.json” to confirm “@angular/router” is included
- If not, run *npm install @angular/router* to add
- Execute *ng generate module appRouting --flat --module=app* from app root
- This will generate a new module called `app-routing.module.ts`

Adding Angular Routing

- Verify that *AppRoutingModule* has been added to the *AppModule* imports
- Replace the *AppRoutingModule* code with the following base content

```
⚠ app-routing.module.ts ×  
src > app > ⚠ app-routing.module.ts > ...  
1  import { NgModule } from '@angular/core';  
2  import { Routes, RouterModule } from '@angular/router';  
3  
4  const routes: Routes = [];  
5  
6  @NgModule({  
7    imports: [RouterModule.forRoot(routes)],  
8    exports: [RouterModule]  
9  })  
10 export class AppRoutingModule { }  
11
```

Adding Angular Routing

- Add a `<router-outlet></router-outlet>` element to the template for `AppComponent`
- Verify the presence of a `<base href="/">` element in `./src/index.html`
- To test, create a new component (or use an existing one)
- In `app-routing.module.ts`, add a new entry to the `routes` collection (called a route configuration)

Adding Angular Routing

- Entry will be an object with two properties:
 - A string path value (called *path*)
 - The component that should be rendered for the defined path (called *component*)
- For example, `{ path: 'landing', component: LandingComponent }`
- If all is set up correctly, on launch and navigation to the configured path, the specified component should be rendered

Adding Angular Routing

- Can add a default path using an empty string for *path* and a redirect
- You can add a “wildcard path” using “`**`” for path
- Routing will use the first match it finds – because of that, order of the routes is important (more specific routes listed first)

```
5
6  const routes: Routes = [
7    { path: 'landing', component: LandingComponent },
8    { path: '', redirectTo: '/landing', pathMatch: 'full' },
9    { path: '**', component: PageNotFoundComponent }
10 ];
11
```

Navigating to a Route

- Couple of options:
 - Add the *routerLink* directive to `<a>` elements
 - Use the *navigate()* method of *Router* service in code
- *routerLink* associates a string path to the hyperlink for navigating to a route
- For example, `Home`

Navigating to a Route

- routerLinkActive is another directive used for styling the active link
- For example,

```
<a routerLink="/landing" routerLinkActive="active">Home</a>
<a routerLink="/orders" routerLinkActive="active">Access Orders</a>
```

- Used to apply a CSS class to a link to style when route selected

Navigating to a Route

- Router service (exported by *RouterModule*) can be used for routing in code
- Includes a method called `navigate`
- Method accepts an array containing destination route path and any route parameters

```
8  }
9  export class PageNotFoundComponent implements OnInit {
10
11  constructor(private router: Router) { }
12
13  ngOnInit(): void {
14  }
15
16  goHome(): void {
17    this.router.navigate(['/landing']);
18  }
19}
20
21
```

Feature Routing Modules

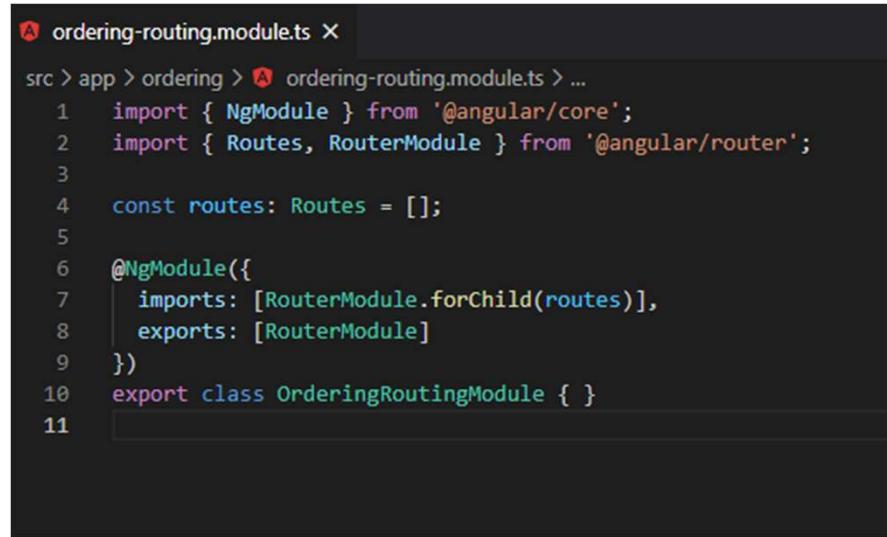

- Instead of using *AppRoutingModule* for all route configuration, can localize routing to our feature modules
- *AppRoutingModule* continues to house application-level routing (e.g., home page, page not found, etc.)
- Each feature module can also define its own routing

Feature Routing Modules

- Routing can be added at time of module creation using the *routing* flag
- For example, *ng generate module <mod-name> --routing*
- Creates <mod-name>-routing.module.ts along with <mod-name>.module.ts

```
ordering-routing.module.ts ✘
src > app > ordering > ordering-routing.module.ts > ...
1 import { NgModule } from '@angular/core';
2 import { Routes, RouterModule } from '@angular/router';
3
4 const routes: Routes = [];
5
6 @NgModule({
7   imports: [RouterModule.forChild(routes)],
8   exports: [RouterModule]
9 })
10 export class OrderingRoutingModule { }
```

Feature Routing Modules

- To add routing to an existing feature module, execute `ng generate module <mod-folder>/<mod-name>Routing --flat --module=<mod-name>`
- This will generate a new module called `<mod-name>-routing.module.ts`

A screenshot of a code editor showing the file `ordering-routing.module.ts`. The code defines a routing module for the `ordering` feature. It imports `NgModule` and `RouterModule` from Angular, creates an array of routes, and defines a module with imports and exports. The code is as follows:

```
ordering-routing.module.ts
src > app > ordering > ordering-routing.module.ts > ...
1 import { NgModule } from '@angular/core';
2 import { Routes, RouterModule } from '@angular/router';
3
4 const routes: Routes = [];
5
6 @NgModule({
7   imports: [RouterModule.forChild(routes)],
8   exports: [RouterModule]
9 })
10 export class OrderingRoutingModule { }
```

Feature Routing Modules

- Feature routing module will have its own route configuration
- Instead of `forRoot`, the feature routing module uses `forChild` to import
- As with `AppRoutingModule`, the `RouterModule` is an import and export

Feature Routing Modules

- The feature module will import the feature routing module
- *AppModule* will import the feature module (enabling the feature routing by extension)
- With routing, the feature module should be placed above the *AppRoutingModule*

```
ordering.module.ts X
src > app > ordering > ordering.module.ts > ...
1  import { NgModule } from '@angular/core';
2  import { CommonModule } from '@angular/common';
3
4  import { OrderingRoutingModule } from './ordering-routing.module';
5
6
7  @NgModule({
8    declarations: [],
9    imports: [
10      CommonModule,
11      OrderingRoutingModule
12    ]
13  })
14  export class OrderingModule { }
```

```
4  import { AppComponent } from './app.component';
5  import { AppRoutingModule } from './app-routing.module';
6  import { LandingComponent } from './landing/landing.component';
7  import { PageNotFoundComponent } from './page-not-found/page-not-found.component';
8  import { OrderingModule } from './ordering/ordering.module';
9
10 @NgModule({
11   declarations: [
12     AppComponent,
13     LandingComponent,
14     PageNotFoundComponent
15   ],
16   imports: [
17     BrowserModule,
18     OrderingModule,
19     AppRoutingModule
20   ],
21   providers: [],
22   bootstrap: [AppComponent]
23 })
24 export class AppModule { }
```

Using Route Parameters

- Route parameters can be used to send additional data to inform a route
- For example, sending the id of a specific order on the order route to enable dynamic display of that order's detail
- The component for the detail route could use the id to look up order details using a service

Using Route Parameters

- The parameter can be added to the *path* value of the route
- For example, { *path*: 'order/:id', *component*: OrderDetailComponent }
- The colon (:) denotes a route parameter
- If multiple parameters are required, separate each with “/”

Using Route Parameters

- The parameter value can be included in the *routerLink* directive
- For example, `<a [routerLink]=“[‘/order’, order.id]”>...`
- Can also be included in the call to the Router service’s navigate method (in code)

```
goToOrder(): void {
  this.router.navigate(['/order', this.order.id]);
}
```

Using Route Parameters

- In the route component, the *ActivatedRoute* service can be used to get information for the currently active route (including parameters)
- *ActivatedRoute* includes a couple of observables for this purpose
- *paramMap* and *queryParamMap* provide access to route parameters and query string parameters respectively

Using Route Parameters

- An alternative to the observables is use of a route snapshot
- Contains a point-in-time snapshot of the current route detail
- The snapshot property of `ActivatedRoute` includes `paramMap` and `queryParamMap` properties
- Represent key-value collections housing parameter values

Child Routes

- Can be used for route orchestration in a container component
- Utilizes a separate `<router-outlet>` element for placement of child routes
- Child route information is defined in the route configuration for the container component using the `children` property

```
5
6  const routes: Routes = [
7  |
8    {
9      path: 'orders',
10     component: OrdersContainerComponent,
11     children: [
12       { path: ':id', component: OrderDetailComponent }
13     ]
14   }
15 ];
```

Route Guards

- In some cases, may want to manage access to or from a given route
- Examples include preventing unauthorized access to a route or verifying with a user before navigating away from a route
- To do so, we leverage an Angular service called a guard

Route Guards

- To create a new guard use `ng generate guard <name>`
- At creation, you will be prompted for the set of interfaces (i.e., guard actions) to be implemented
- Angular will scaffold a new TypeScript class for the guard accordingly

Guard Types

- Includes:
 - *CanActivate* – Controls access to a route
 - *CanActivateChild* – Controls access to a route's child routes
 - *CanDeactivate* – Controls navigation away from a route
 - *CanLoad* – Controls access to a lazy-loaded route

General Guard Functionality

- Parameters provide information about current and target routes (route parameters, query string parameters, etc.)
- If all assigned guards of a specific type return true, routing type proceeds
- If any assigned guard returns false, routing type will be cancelled

General Guard Functionality

- Guards can use the *Router* service to navigate to an alternate route
- Or can return a *UrlTree* which will cancel current route and begin a new one
- Both synchronous and asynchronous versions are available

General Guard Functionality

- To assign a guard to a route, update the route configuration
- In addition to *path* and *component* properties, there are properties for each guard type (named after type)
- Properties are of array type – allows assignment of multiple guards of a given type

Lazy-Loaded Routes

- As application complexity grows, bundle size can grow as well
- If large enough, can impact load or startup performance
- For routes that may be accessed with less frequency, lazy-loading can help

Lazy-Loaded Routes

- Modules for lazy-loaded routes are bundled separately, reducing main application bundle size
- Those modules can get loaded by request – once requested, will remain loaded for the session
- To lazy-load a module, we do not include it in the *imports* property of another module

Lazy-Loaded Routes

- We load in code as part of the route configuration
- Uses an additional property in the config called *loadChildren*
- Leverages a method called *import* that returns a *Promise*
- On completion of the *Promise*, the module is loaded (in response to route request)

```
{  
  path: 'contactus',  
  loadChildren: () => import('./contact-us/contact-us.module').then(m => m.ContactUsModule),  
  ...  
}
```

Guarding Lazy-Loaded Routes

- To guard lazy-loaded routes, we use a guard that implements *CanLoad*
- Operates similarly to the other guards:
 - Provides parameters with details about the route
 - Returns either a boolean or a *UrlTree*
 - Provides both sync and async options
- In route configuration, applied in the *canLoad* property (an array)

Exercise 8

- Start with the ordering app that you modified in exercise 7
- Add Angular routing to the application
- Add routing to the ordering module
- Replace the content of the order component with a <router-outlet></router-outlet> element
- Create a route for /orders which routes to the order header component (which lists headers)
- Create a route for the order detail component using order header id as a parameter
- Create a default route to route to “/orders”
- Add a link column to the table in order header component to use order detail route to drilldown into detail for the order
- Update the order detail component to use a table-like structure for display of the order’s detail records
- Use the service or hard-coded data to capture order header and associated order details for each (don’t worry about totals matching up for now)
- Test each route – confirm ability to navigate to order header list and order details
- Use the parameter on the route in the order details component to pull the order’s details for display
- Provide a return link from order details back to the orders/ route
- Add a route guard that uses a hard-coded boolean to check if user is “authenticated” – if false, on attempts to hit either the /orders or /orders/<id> route, send user to landing page
- In the app level routing, create a lazy-loaded route for a “contact us” page and create a wildcard route for “page not found”

Exercise 8

Response to “/orders” route

Orders				
Order Number	Description	Customer Name	Total	
...	\$X.XX	Details
...	\$X.XX	Details

Toggle

Exercise 8

Response to “/orders/<id>” route

Order Details (Order #<Order Number>)		
Product Number	Quantity	Total
...	...	\$X.XX
...	...	\$X.XX

Angular Services

Purpose

- Angular services are TypeScript classes with specific purposes
- Intended to house and provide shared functionality for reuse across the app
- No requirement to use services in your Angular app
- However, considered a best practice

Purpose

- Used for tasks like pulling data from an API, specialized validation or logging
- Logic could be coded directly in components
- However, components should focus solely on view management

Purpose

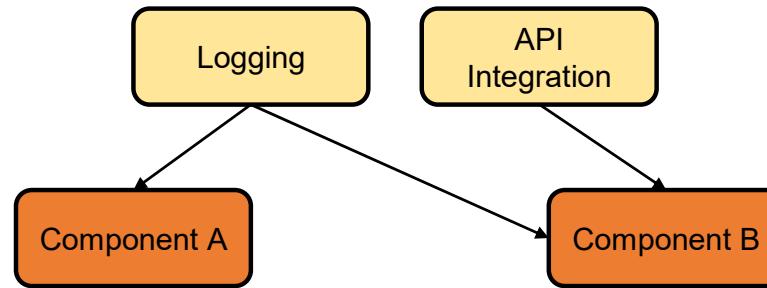

- Capturing logic in service:
 - Keeps components smaller and easier to manage
 - Enables support for multiple components
 - Facilitates testing
 - Promotes modularity

Dependency Management

- To keep components modular, leverage reusable logic from other classes
- Classes with reusable logic are known as dependencies

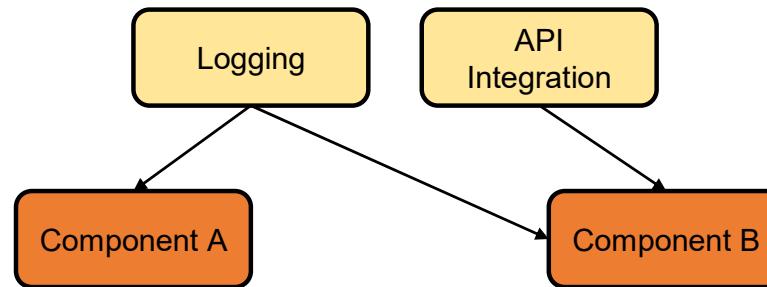

Dependency Management

- One option is to explicitly create new instances of dependencies as needed
- Requires extra code
- Could waste memory if new instance created in every component where logic is required

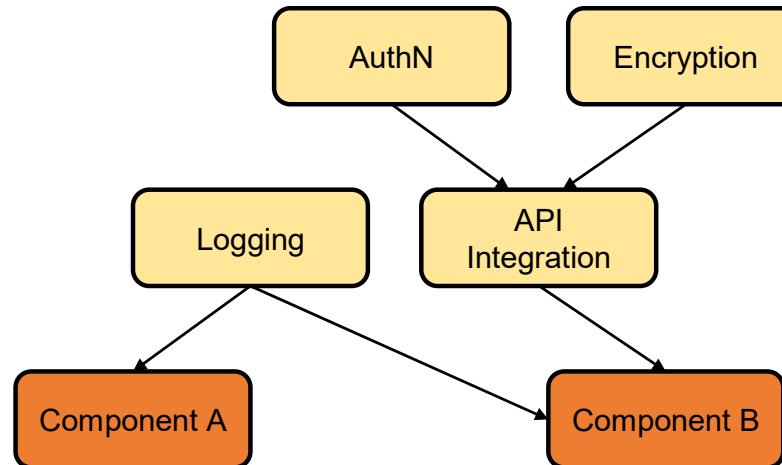

Dependency Management

- Exacerbated if dependency also has downstream dependencies
- When testing, requires creation and configuration of the dependency tree
- And a dependency used for API access requires access to the API in the test
- Difficult to test the component logic directly and in isolation (true unit test)

Dependency Injection

- Instead of explicitly managing dependencies, Angular allows us to delegate
- Provides a rich Dependency Injection mechanism to help automate management
- Greatly loosens coupling between components and dependencies

Dependency Injection

- Dependency reference added to constructor of consuming class
- When consuming class is created, injector checks for existing dependency instance
- If found, reuses; otherwise, creates and returns new singleton instance
- Adds newly created instance to pool of instances for future use

```
orders-container.component.ts ✘
src > app > ordering > orders-container > orders-container.component.ts > ...
1 import { Component, OnInit, ViewChild } from '@angular/core';
2 import { Order } from 'src/app/page-not-found/page-not-found.component';
3 import { DataService } from 'src/app/services/data.service';
4 import { OrderDetailComponent } from '../order-detail/order-detail.component';
5
6 @Component({
7   selector: 'app-orders-container',
8   templateUrl: './orders-container.component.html',
9   styleUrls: ['./orders-container.component.css']
10 })
11 export class OrdersContainerComponent implements OnInit {
12   @ViewChild('orderDetail') orderDetail: OrderDetailComponent;
13
14   constructor(private dataService: DataService) { }
15
16   ngOnInit(): void {
17   }
18
19   onShip(isShipped: boolean): void {
20     if (isShipped) {
21       window.alert(`Shipped order number ${this.orderDetail.orderNumber}`);
22     }
23   }
24
25   getOrders(): Order[] {
26     return this.dataService.getOrders();
27   }
28
29 }
30 }
```

Creating Custom Services

- To create a custom service, we use *ng generate service <name>*
- Angular creates a TypeScript file for the service called *<name>.service.ts*
- Be aware – service will be created in folder where *ng generate* is executed
- Not registered with a module – instead, registered with an injector

@Injectable() Decorator

- Service is defined by TypeScript class decorated with `@Injectable()`
- Accepts an optional object parameter that includes property called *providedIn*
- By default, value for property will be ‘root’

@Injectable() Decorator

- Indicates service registered with root injector
- When registered with root injector, available across app
- `@NgModule` decorator includes *providers* property
- Can also register with root injector by adding to *providers* in `AppModule`

```
3
4  @Injectable({
5    |   providedIn: 'root'
6  })
7  export class DataService {
8
9    constructor() { }
10
11   getOrders(): Order[] {
12     // Logic to retrieve orders
13     return [] as Order[];
14   }
15 }
16 }
```

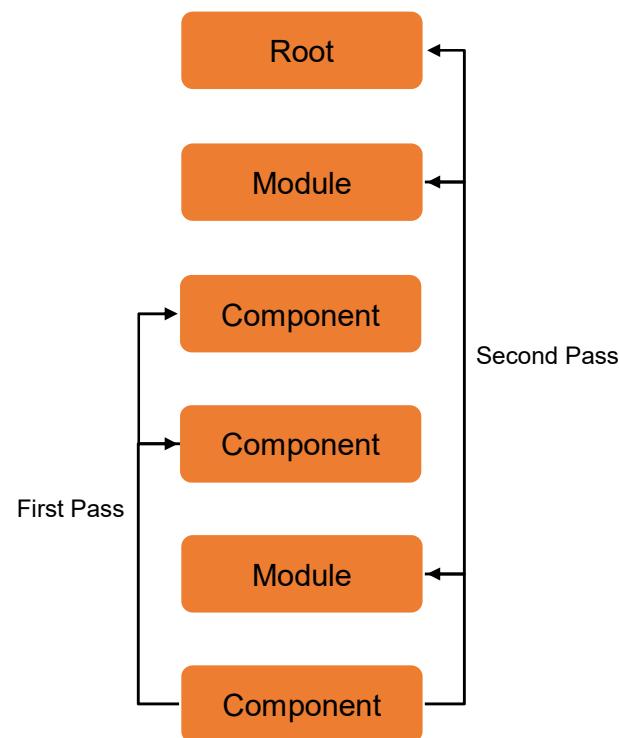

The Injector Tree

- Components & modules also provide injectors
- The set of available injectors represents a hierarchy used during resolution
- When encountering a dependency in a constructor, Angular searches this tree looking for a provider to handle it

The Injector Tree

The Injector Tree

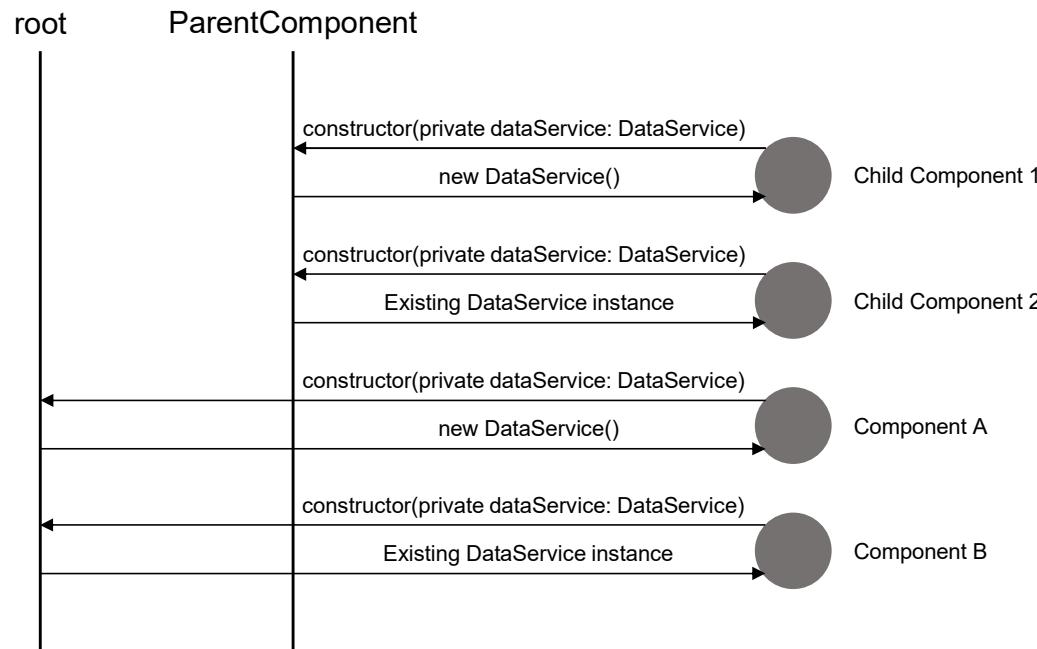

- We've already seen the *providers* property in `@NgModule()`
- There is also a *providers* property available in `@Component()`
- With `@Component()`, service registered in *providers*:
 - Can be shared with child components
 - Can create multiple copies every time component is rendered – scoped to instance

The Injector Tree

- Same service can be registered with a component and root injectors
- Angular uses closest ancestor for dependency resolution

Restricting Dependency Injection

- `@Host()` decorator restricts injector lookup to local and parent only
- If unable to find a match, will not bubble up – will throw exception instead
- `@Optional()` decorator will return null for dependency instead of exception
- Obviously, service calls against a null reference would fail

Restricting Dependency Injection

- `@Self()` decorator restricts injector lookup to local component only
- `@Self()` can also be combined with `@Optional()`
- `@SkipSelf()` decorator skips local injector and searches up the hierarchy
- For example:

constructor(@Host() @Optional() private dataService: DataService)

Overriding Providers

- As discussed, the *providers* property can also be used for service injection
- Accepts one or more service classes
- Also, accepts an object used to designate how service instances are created by the injector

Overriding Providers

providers: [DataService]

is equivalent to

providers: [{ provide: DataService, useClass: DataService }]

Overriding Providers

- *provide* property defines what consumers use in their constructor
- Second property defines what will be provided to consumers as implementation on dependency resolution
- Second property can be one of:
 - *useClass*
 - *useFactory*
 - *useValue*

Overriding Providers

- `useClass` can be used to override implementation with a different class
- For example,

```
providers: [{ provide: DataService, useClass: MockDataService }]
```

Overriding Providers

- *useFactory* can be used to override implementation with a dynamically generated service instance
- *deps* can be used to inject downstream dependencies for instance types returned from factory method
- For example,

```
providers: [{
  provide: DataService,
  useFactory: dataServiceFactory(),
  deps: [HttpClient]
}]
```

Overriding Providers

- *useValue* can be used to provide a value instead of class instance
- Value returned could be a simple value or a dynamically-defined object
- Allows return of constants as part of dependency resolution

Asynchronous Data

Working with Data

- Often, an Angular app will make calls to an API for data operations
- The API is likely off box and out of process
- Because of that, API operations can take some time to complete

Working with Data

- Rather than block the UI thread, the calls are made asynchronously
- App can move on to other processing/interaction with user
- When data operation completes, can be notified for results processing

Asynchronous Calls

- Traditionally, we've had 3 options for handling:
 - Callbacks
 - Promises
 - *async/await*

Callbacks

- Function reference passed to a method executing asynchronous activity
- When the async processing finishes, calls the provided method to notify
- Callback method can then be used to process results or move to next step in sequence

Callbacks

- When working with a single async operation, this approach is OK
- With multiple async operations in sequence, the code can get ugly quickly
- Often results in several nested levels of calls that can be hard to read and maintain

Promises

- Provide an improvement over callbacks
- Multiple asynchronous operations can be logically chained together
- Also, operations can be split off and results can be combined and resolved together as a unit

Promises

- To use, create a new instance of the *Promise* type
- Constructor accepts *resolve* and *reject* method references
- The *resolve* method reference is a callback executed on success
- The *reject* method reference is a callback executed on failure

Promises

- While still technically using callbacks, the code becomes much cleaner
- Multiple async operations are chained using `then()`
- Set of chained operations might look like this:

```
this.getOrder(orderNumber)
  .then((o: Order) => Promise.all([this.getShippingInformation(o), this.getTaxInformation(o)]))
  .then((result: [ShippingInformation, TaxInformation]) => combine(result));
```

async/await

- “Syntactic sugar” for Promises
- Code can call asynchronous methods in sequence (like other methods)
- `await` is only valid in a method defined as `async`

```
async getAllOrderInformation(orderNumber): Order {  
    const order = await this.getOrder(orderNumber);  
    order.ShippingInformation = await this.getShippingInformation(order);  
    order.TaxInformation = await this.getTaxInformation(order);  
    return order;  
}
```

Issues with Promises

- Promises can work for some use cases
- However, there are some limitations:
 - Cannot be canceled
 - Are immediately executed – executed at point of call
 - Represent one-time operations only – no easy way to retry or handle a “stream” of results

Observables

- Observables are defined in the RxJS library
- Support asynchronous and event-based interaction
- Offer similar capabilities as Promises with additional benefits

Observables

- An observable is an object that maintains a list of dependent observers
- Informs observers about state changes through async emit of events
- Observers subscribe to be notified and react to the changed state
- Subscribed observers continue to “listen” and be notified until either:
 - An unsubscribe
 - Observable is destroyed

Observables

- Observables return a stream of events
- Observers receive prompt notification of a new occurrence
- The stream can be a combination of different async operations
- Operators exist to enable things like sequencing vs. parallel, filtering, etc.

Reactive Functional Programming

- Requires the following:
 - An observable
 - One or more observers
 - A timeline
 - A stream of events
 - A set of composable operators
- Using RxJS and Observables, can apply async subscriptions and transformations to an observable stream of events or state changes

RxJS Operators

- RxJS includes extensive set of operators (<https://rxjs.dev/guide/operators>)
- Categories include creation, transformation, filtering, join, error handling and utility operators
- Enable rich composition in the logic used to handle state changes or events

of

- Wraps a set of items into an observable sequence
- Emits each argument passed to it and then completes
- Each argument is treated as an implicit *next()* – the observable's way of sending a new notification to subscriber(s)

of

```
observables.component.ts X
src > app > observables > observables.component.ts > ...
1 import { Component, OnDestroy, OnInit } from '@angular/core';
2 import { of, Subscription } from 'rxjs';
3
4 @Component({
5   selector: 'app-observables',
6   templateUrl: './observables.component.html',
7   styleUrls: ['./observables.component.css']
8 })
9 export class ObservablesComponent implements OnInit, OnDestroy {
10
11   sequence$ = of(10, 20, 30, 40);
12   subscription: Subscription;
13
14   constructor() { }
15
16   ngOnInit(): void {
17     this.subscription = this.sequence$.subscribe(value => console.log(value));
18   }
19
20   ngOnDestroy(): void {
21     this.subscription?.unsubscribe();
22   }
23
24 }
25
```

observables works!

The screenshot shows the Chrome DevTools Console tab. The 'Console' tab is selected. The output area displays the following log entries:

```
> (4) [25, 30, 35, 40]
10
20
30
40
Angular is running in development mode. Call enableProdMode() to enable production mode.
[WDS] Live Reloading enabled.
```

from

- Converts almost anything to an Observable
- Accepts an *Array*, a *Promise*, an iterable object, etc.
- As with *of()*, each argument is treated as an implicit *next()*
- Unlike *of()*, *from()* flattens – e.g., emits a *next()* separately for each element of an *Array*

from

```
observables.component.ts ✘
src > app > observables > observables.component.ts > ...
1 import { Component, OnDestroy, OnInit } from '@angular/core';
2 import { from, Subscription } from 'rxjs';
3
4 @Component({
5   selector: 'app-observables',
6   templateUrl: './observables.component.html',
7   styleUrls: ['./observables.component.css']
8 })
9 export class ObservablesComponent implements OnInit, OnDestroy {
10
11   sequence$ = from([10, 20, 30, 40]);
12   subscription: Subscription;
13
14   constructor() { }
15
16   ngOnInit(): void {
17     this.subscription = this.sequence$.subscribe(value => console.log(value));
18   }
19
20   ngOnDestroy(): void {
21     this.subscription?.unsubscribe();
22   }
23
24 }
25
```

observables works!

A screenshot of the browser's developer tools Console tab. The tab is labeled 'Console'. The output shows the following logs:

```
[25, 30, 35, 40]
10
20
30
40
Angular is running in development mode. Call enableProdMode() to enable production mode.
[WDS] Live Reloading enabled.
```

- Method that can be called on an Observable
- Combines a sequence of operations against event or notification data
- Able to “pipe” results of one operator to another (depending on the operator)
- Final `subscribe()` will receive result from all operators being applied

map

- Projects data received into a new version or value
- Returns an Observable that wraps the updated result
- Can be used in a *pipe()* to transition event data as it flows through a sequence of steps

filter

- Filters data received in Observable stream according to a provided predicate
- Values that meet provided predicate condition are included (boolean)
- Returns an Observable that wraps the set of filtered values

Multiple Operators

```
ngAfterViewInit(): void {
  const logger = fromEvent(this.keyInput.nativeElement, 'keyup');
  this.subscription = logger.pipe(
    map((evt: KeyboardEvent) => evt.key.charCodeAt(0)),
    filter(code => {
      return !(code < 48 || code > 57);
    }),
    tap(digit => this.keys += String.fromCharCode(digit))
  ).subscribe(_ => {
    const value = +this.keys;
    if (value > 999999) {
      console.log('Whoa - that is way too high!!');
    }
  });
}
```

concatAll

- Joins and flattens a set of Observables into a sequence executed serially
- Subscribes to each “inner” Observable only after previous has completed
- Merges all results into a single Observable

```
ngOnInit(): void {
  this.subscription = fromEvent(document, 'click')
    .pipe(
      map(_ => interval(1000).pipe(take(4))),
      concatAll()
    ).subscribe(x => console.log(x));
}
```

- Executes an array of Observables in parallel
- Does not complete until all Observables in the array complete
- Amount of time required to complete will be the duration of the longest Observable

```
ngOnInit(): void {
  this.subscription = forkJoin([
    this.service.makeRequest('Request One', 8000),
    this.service.makeRequest('Request Two', 1000),
    this.service.makeRequest('Request Three', 3000)
  ]).subscribe(results => {
    this.result1 = results[0];
    this.result2 = results[1];
    this.result3 = results[2];
  });
}
```

Demo

HTTP Client

- Used in our Angular services for integrating with a REST API
- Available through import of *HttpClientModule* (usually in *AppModule*)
- Includes methods to support standard CRUD operations

- Injected as a dependency in our service constructor
- Methods supported include:
 - `get()` – performs a GET operation to retrieve data
 - `post()` – performs a POST operation to add data
 - `put()` – performs a PUT operation (typically for updating data)
 - `delete()` – performs a DELETE operation to delete data

HTTP Client

- All return an Observable for async handling
- Support providing a request body (where applicable) in the form of an object
- Also support specification of custom headers (as required)

Angular In-Memory Web API

- In some cases, the API may be developed separately and in parallel
- In-memory Web API enables work to continue on the UI while in progress
- Provides a fake server that mimics all CRUD operations of a REST API
- Backed with a transient collection to provide “database”

Angular In-Memory Web API

- First install using `npm install angular-in-memory-web-api --save-dev`
- Create a service that implements the `InMemoryDbService` interface
- Implement the `createDb()` method to build out in-memory “database”

Angular In-Memory Web API

- `createDb()` returns an object with one or more key-value pairs
- Each key represents a “table”
- Each value is a collection of objects representing “table” rows
- Row object structure should match up with application models

Angular In-Memory Web API

```
⚠ data.service.ts ×  
src > app > ⚠ data.service.ts > ...  
1  import { Injectable } from '@angular/core';  
2  import { InMemoryDbService } from 'angular-in-memory-web-api';  
3  
4  @Injectable({  
5    providedIn: 'root'  
6  })  
7  export class DataService implements InMemoryDbService {  
8  
9    constructor() {}  
10  
11   createDb(): any {  
12     return {  
13       orders: [  
14         { id: 1, customerId: 1, total: 199.99 },  
15         { id: 2, customerId: 2, total: 37.55 },  
16         { id: 3, customerId: 1, total: 54.89 },  
17         { id: 4, customerId: 3, total: 119.00 },  
18         { id: 5, customerId: 4, total: 1045.87 }  
19       ],  
20       orderDetails: [  
21         { id: 1, orderId: 1, productId: 2, quantity: 18 },  
22         { id: 2, orderId: 1, productId: 110, quantity: 1 },  
23         { id: 3, orderId: 1, productId: 1, quantity: 14 },  
24         { id: 4, orderId: 2, productId: 99, quantity: 187 }  
25       ]  
26     };  
27   }  
28 }  
29 }
```

Angular In-Memory Web API

- Import `HttpClientInMemoryWebApiModule`
- On import, call `forRoot()`, passing in service name that provides mock data
- For example, `HttpClientInMemoryWebApiModule.forRoot(DataService)`

Angular In-Memory Web API

- *HttpClientModule* must be imported before in-memory API module
- Can use environments to dynamically manage between dev and prod
- Enables specification of a delay in milliseconds (to mimic latency)

```
],
imports: [
  BrowserModule,
  HttpClientModule,
  !environment.production ? HttpClientInMemoryWebApiModule.forRoot(DataService, { delay: 1000 }) : [],
  HeroesModule
],
providers: [
```

Angular In-Memory Web API

- URL for mock API will be in form of “`api/<entity>`”
- `<entity>` corresponds to keys used in `createDb()` method (e.g., `orders`)
- All other service code for API integration can be written normally

Exercise 9

- Start with the ordering app that you modified in exercise 8
- Move your hard-coded order header and order detail data into a data service (if not already)
- Add Angular in-memory Web API to that service to simulate mock DB
- Create another service for order operations – when complete, you'll have 2 services (one for in-memory DB and one for API operations for orders)
- Make sure data retrieval methods exposed in order service are exposed as Observables
- Convert existing data retrieval operations employed on your routes to calls to the HTTP API for order data integration
- Verify that all operations continue to function correctly
- NOTE: Make sure that your components can correctly handle any potential delays in return from the API calls (i.e., until API method completes, bound object may be null)
- You can use { delay: <millisecond value> } as a second parameter to HttpClientInMemoryWebApiModule import in AppModule to simulate delay

HTTP Interceptors

- Usually, API's require an “Authorization” header (probably in the form of “Bearer <JWT>”)
- Sent on request and used by API to verify authorization to make call
- This custom header can be added to every API method call

HTTP Interceptors

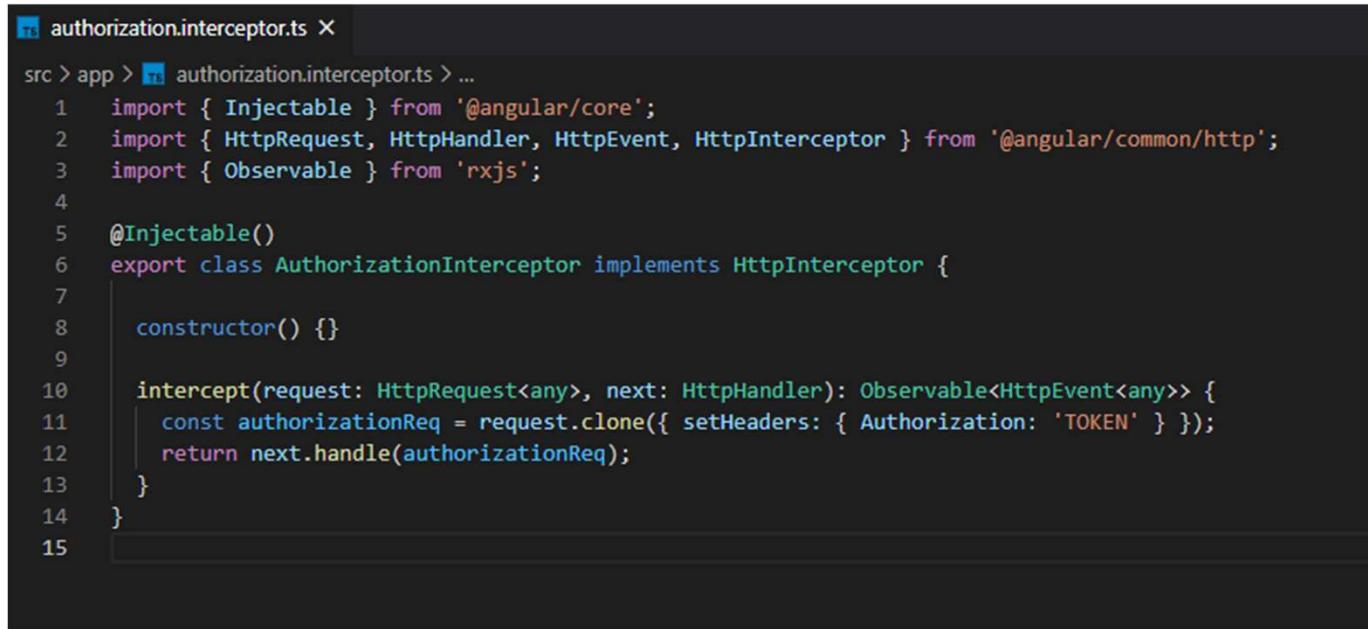

- However, can lead to an extensive amount of repeat code
- Instead, can use an HTTP interceptor to automate
- Intercepts HTTP requests/responses originating from *HttpClient*
- Enables designation of configuration or activity that should occur for each

HTTP Interceptors

- Use `ng generate interceptor <name>` to create
- Provides a service that implements `HttpInterceptor`
- Provides implementation for the `intercept()` method to enable

```
authorization.interceptor.ts X
src > app > authorization.interceptor.ts > ...
1  import { Injectable } from '@angular/core';
2  import { HttpRequest, HttpHandler, HttpEvent, HttpInterceptor } from '@angular/common/http';
3  import { Observable } from 'rxjs';
4
5  @Injectable()
6  export class AuthorizationInterceptor implements HttpInterceptor {
7
8    constructor() {}
9
10   intercept(request: HttpRequest<any>, next: HttpHandler): Observable<HttpEvent<any>> {
11     const authorizationReq = request.clone({ setHeaders: { Authorization: 'TOKEN' } });
12     return next.handle(authorizationReq);
13   }
14 }
15
```

HTTP Interceptors

- *intercept()* accepts two parameters:
 - *HttpRequest* object representing current request
 - *HttpHandler* object denoting next interceptor in chain (if applicable)
- Enables chaining together of multiple interceptors (e.g., authorization + logging)
- Last interceptor in the chain is *HttpBackend*

HTTP Interceptors

- To use, must be registered with a module (usually `AppModule`)
- Likely will not leverage `providedIn` property of `@Injectable()`
- Instead, will use `providers` property of `@NgModule()`

HTTP Interceptors

- The object passed to *providers* includes valuable config options
- This config is what enables the chaining capability
- Also note – because of chaining, order of import is important

```
  },
  providers: [
    { provide: HTTP_INTERCEPTORS, useClass: AuthorizationInterceptor, multi: true }
  ],
  bootstrap: [AppComponent]
```

Unsubscribing from Observables

- Good practice to unsubscribe from Observables
- Helps prevent memory leaks
- Couple of options:
 - Explicitly unsubscribing
 - Using async pipe

Unsubscribing from Observables

- When subscribing, can store a reference to the subscription
- In `ngOnDestroy()`, can use the `unsubscribe()` method to unsubscribe

```
export class ObservablesComponent implements OnInit, OnDestroy {

  result1: string;
  result2: string;
  result3: string;
  subscription: Subscription;

  constructor(private service: MyService) { }

  ngOnInit(): void {
    this.subscription = forkJoin([
      this.service.makeRequest('Request One', 8000),
      this.service.makeRequest('Request Two', 1000),
      this.service.makeRequest('Request Three', 3000)
    ]).subscribe(results => {
      this.result1 = results[0];
      this.result2 = results[1];
      this.result3 = results[2];
    });
  }

  ngOnDestroy(): void {
    this.subscription?.unsubscribe();
  }
}
```

Unsubscribing from Observables

- async pipe provides alternative to subscribing to an Observable
- In template, can pipe the Observable using `<observable> | async`
- This handles both subscription and unsubscription for us

Forms in Angular

Web Forms

- Web applications use forms to gather input from users
- When building apps, remember the adage “if a user can do it, they’ll try”
- Need to implement a rich validation strategy for data input (both client-side and server-side)

Web Forms

- Angular offers two options for building our forms:
 - Template-driven – what we've been using so far
 - Reactive

Template-Driven vs. Reactive

Feature	Template-Driven	Reactive
Form model setup	Implicit, created by directives	Explicit, created in code
Data model	Unstructured and mutable	Structured and immutable
Predictability	Asynchronous	Synchronous
Form validation	Directives	Functions
Testability	More difficult	Less difficult
Scalability	Considered worse	Considered better
Ease of use	Simpler	More complex

Template-Driven and ngModel

- Already discussed *FormsModule* and the *ngModel* directive
- We saw that *ngModel* is one option for adding two-way data binding to our forms

Reactive Forms

- Will leverage the *ReactiveFormsModule*
- Will build out our forms in code, in the component class
- Will link our HTML elements in the template to the coded form objects
- Will utilize reactive techniques to manage state changes and validation

Reactive Forms

- Key classes used in Reactive forms approach include:
 - *FormControl* – represents individual form control (e.g., input element)
 - *FormGroup* – represents collection of form controls (static)
 - *FormArray* – represents collection of form controls (dynamic)
- Available in the `@angular/forms` npm package

Reactive Forms

- In code, can build out a set of controls as a group using *FormGroup*
- Constructor takes a set of key-value pairs for the *FormControl* objects
- Key will be a unique name for form control
- Value will be the associated *FormControl* object

Reactive Forms

- *formGroup* used to associate a `<form>` element in component HTML to `FormGroup` object
- *FormControlName* used to associate a form control in the HTML to a `FormControl` in the group

Reactive Forms

- Can reference *FormControl* object in HTML expressions and directives using `<form-group-name>.controls.<form-control-name>.<property-name>`
- For example, `orderForm.controls.description.value`
- Alternatively, create getter properties for controls to allow shortened syntax

```
order-form.component.html x
src > app > order-form > order-form.component.html > ...
1  <h1>Enter New Order</h1>
2  <form [formGroup]="orderForm" (ngSubmit)="submit()">
3    <div>
4      <label>Order Description:</label>
5      <input type="text" name="description" placeholder="description" formControlName="description" />
6    </div>
7    <div>
8      <p>Entered description: {{orderForm.controls.description.value}}</p>
9    </div>
10   </form>
11
```

Reactive Forms

order-form.component.ts X

```
src > app > order-form > order-form.component.ts > ...
2   import { AbstractControl, FormControl, FormGroup } from '@angular/forms';
3
4   @Component({
5     selector: 'app-order-form',
6     templateUrl: './order-form.component.html',
7     styleUrls: ['./order-form.component.css']
8   })
9   export class OrderFormComponent implements OnInit {
10
11   orderForm = new FormGroup({
12     description: new FormControl('Default')
13   });
14
15   constructor() { }
16
17   ngOnInit(): void {
18   }
19
20   get description(): AbstractControl {
21     return this.orderForm.controls.description;
22   }
23
24   submit(): void {
25
26   }
27
28 }
29
```

order-form.component.html X

```
src > app > order-form > order-form.component.html > ...
1   <h1>Enter New Order</h1>
2   <form [formGroup]="orderForm" (ngSubmit)="submit()">
3     <div>
4       <label>Order Description:</label>
5       <input type="text" name="description" placeholder="description" formControlName="description" />
6     </div>
7     <div>
8       <p>Entered description: {{description.value}}</p>
9     </div>
10    </form>
11
```

Providing Feedback on Input Status

- Angular automatically applies the following classes to communicate control status (or a combination of them):

Class	Purpose
ng-untouched	User has not yet interacted with control
ng-touched	User has interacted with control
ng-dirty	Control has a value
ng-pristine	Control does not yet have a value
ng-valid	Value of control is valid (according to defined validation rules)
ng-invalid	Value of control is not valid

Adding Form Validation

- *FormControl* constructor accepts a parameter for default value
- It accepts a second parameter for one or more validators to be applied to the control
- Possible options include required input, minimum/maximum length, minimum/maximum value
- Also supports email validation as well as *RegExp* pattern validation

```
})
export class OrderFormComponent implements OnInit {
  orderForm = new FormGroup({
    description: new FormControl('Default', [Validators.required, Validators.minLength(10), Validators.maxLength(25)])
  });
  constructor() { }
  ngOnInit(): void {
  }
}
```

Adding Form Validation

- With definition in place, can see immediate effects on interaction with form

Providing User with Visual Cues

- *FormGroup* and *FormControl* objects have status properties (like status classes previously mentioned)
- Invalid status for one or more controls rolls up to invalid status for form
- Can use to prevent form submission if any input is invalid

```
order-form.component.html X
src > app > order-form > order-form.component.html > form > button
1  <h1>Enter New Order</h1>
2  <form [formGroup]="orderForm" (ngSubmit)="submit()">
3  | <div>
4  | | <label>Order Description:</label>
5  | | <input type="text" name="description" placeholder="description" formControlName="description" />
6  | </div>
7  | <div>
8  | | <p>Entered description: {{description.value}}</p>
9  | </div>
10 <button type="submit" [disabled]="!orderForm.valid">Create Order</button>
11 </form>
12
```

Enter New Order

Order Description:

Entered description: First

Create Order

Providing User with Visual Cues

- *FormControl* objects can use status properties to add helper messages
- Can use valid or invalid for general “something’s wrong” message
- Or can use the errors collection on the input to fine tune messaging

```
order-form.component.html X
src > app > order-form > order-form.component.html > ...
1  <h1>Enter New Order</h1>
2  <form [formGroup]="orderForm" (ngSubmit)="submit()">
3    <div>
4      <label>Order Description:</label>
5      <input type="text" name="description" placeholder="description" formControlName="description" />
6      <span class="help-block" *ngIf="description.touched && description.errors?.required">Description is required</span>
7      <span class="help-block" *ngIf="description.touched && description.errors?.minlength">Description must be at least 10 characters long</span>
8      <span class="help-block" *ngIf="description.touched && description.errors?.maxlength">Description must no more than 25 characters long</span>
9    </div>
10   <div>
11     <p>Entered description: {{description.value}}</p>
12   </div>
13   <button type="submit" [disabled]="!orderForm.valid">Create Order</button>
14 </form>
```

Dynamic Forms

- Using *FormArray*, can add controls dynamically to our forms
- Can create as part of *FormGroup* using `<prop-name>: new FormArray([])`
- If referenced via property and cast as *FormArray*, can use standard array methods like `push()` to manage

Dynamic Forms

- *FormArray* elements can contain individual *FormControl* objects
- Can also contain *FormGroup* objects (e.g., row-level edits in dynamic table)
- Will look at how to implement in next exercise

Enter New Order

Order Description: First quarter order 

Line Items:

Product Number	Quantity
ABC123	14
DEF456	8
GHI999	100.4
Product Number	0

[Add Line Item](#)

Entered description: First quarter order

[Create Order](#)

Manipulating Form Data

- *FormGroup* provides two methods for changing form data programmatically:
 - *setValue* – replaces all controls
 - *patchValue* – updates a specific subset of the controls
- Methods take key-value pairs representing control name and target value
- To pull entire set of form data (e.g., on submit), use `<form-name>.value`

Manipulating Form Data

```

populateForm(): void {
  if (this.orderDetails.length < 2) {
    this.orderDetails.push(this.fb.group({
      productNumber: [''],
      quantity: [0]
    }));
  }
  this.orderForm.setValue({
    description: 'Auto-populated',
    orderDetails: [
      { productNumber: 'AAA111', quantity: 13 },
      { productNumber: 'BBB222', quantity: 99 }
    ]
  });
}

resetOrderDetailQuantities(): void {
  this.orderForm.patchValue({
    orderDetails: [
      { quantity: 100 },
      { quantity: 100 }
    ]
  });
}

submit(): void {
  console.log(this.orderForm.value);
}

```

Enter New Order

Order Description:

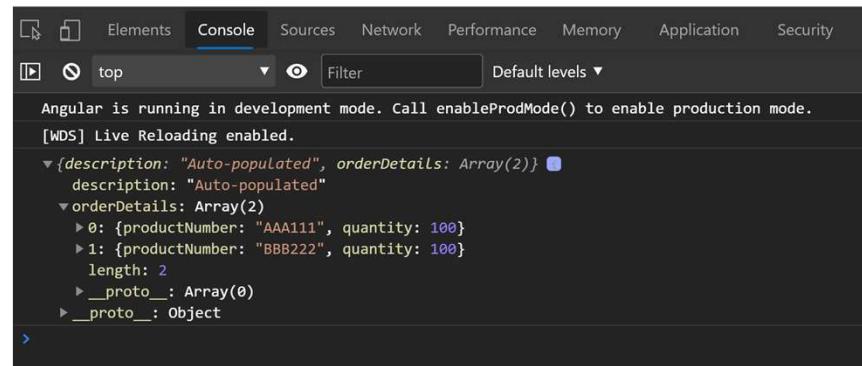

Line Items:

Product Number	Quantity
AAA111	100
BBB222	100

[Add Line Item](#)

Entered description: Auto-populated

[Create Order](#) [Auto-Populate](#) [Reset Order Quantities](#)

Making Form Reactive

- *FormControl* objects provide two Observable properties:
 - *statusChanges* – notifies when status of control changes (e.g., invalid to valid)
 - *valueChanges* – notifies when value of control changes
- Could be used to proactively display hints for validation rules as entered
- Could also be used to check back-end for duplicate input
- Be aware of potential performance implications of complex logic on change

Creating Custom Validator

- Can create a custom validator for your specific model
- To do so, create a class with a static method that accepts form control
- Return either *ValidationErrors* or null

Creating Custom Validator

- *ValidationErrors* represents key-value collection of validation errors
- Apply as validator in *FormBuilder* code
- Optionally look for validation key in collection of control errors for error message display

```
src > app > description.validator.ts > ...
1 import { AbstractControl, ValidationErrors } from '@angular/forms';
2
3 export class DescriptionValidator {
4   static cannotContainMeanWords(control: AbstractControl): ValidationErrors | null {
5     if ((control.value as string).toLowerCase().includes('stupid')) {
6       return { cannotContainMeanWords: true };
7     }
8     return null;
9   }
10 }
11
```

Creating Custom Validator

```
private buildForm(): void {
  this.orderForm = this.fb.group({
    description: ['Default', [
      Validators.required,
      Validators.minLength(10),
      Validators.maxLength(25),
      DescriptionValidator.cannotContainMeanWords
    ]],
    orderDetails: this.fb.array([
      this.fb.group({
        productNumber: [''],
        quantity: [0]
      })
    ])
  });
}
```

```
<span class="help-block" *ngIf="description.touched && description.errors?.maxLength">Description must no more than 25 characters long</span>
<span class="help-block" *ngIf="description.touched && description.errors?.cannotContainMeanWords">Whoa, watch the sailor mouth!</span>
<span *ngIf="showDescriptionHint">Description should be at least 10 and no more than 25 characters long</span>
</div>
```

Demo

Testing in Angular

Types of Testing

- There are multiple types of testing for an Angular app
 - Unit testing
 - Integration testing
 - E2E (End-to-end) or system testing
 - Performance testing
 - User acceptance testing
 - ...

Philosophy of Testing

- Whenever possible, we automate
- Takes time and extra coding to build out the test suites
- However, in the long run, often leads to higher quality and efficiency gains

Philosophy of Testing

- Automation allows testing to be wired into the software delivery pipeline
- Quality gates at various stages help to ensure defects are discovered earlier
- The earlier a defect is discovered, the cheaper it is to fix

Philosophy of Testing

- As mentioned, our ability (or inability) to test can speak to quality of design
- If something is difficult to test, it might be because its design is not optimal
- Perhaps there is tight coupling between elements of the system that will ultimately lead to brittleness

Philosophy of Testing

- Automated testing can help us protect against regression
- Tests can also represent an excellent source of system documentation
- Whether “test first”, “test after” or “test as you go”, testing is a valuable use of time

Discussion – So Why Don't We Test More?

Testing an Angular App

- Unit testing is often performed using tools like Karma/Jasmine or Jest
- E2E (end-to-end) testing may be performed using tools like Protractor
- Often, a logical grouping of tests will be organized in a “test suite”
- Each suite can represent tests for a specific feature

Testing an Angular App

- Karma/Jasmine are very popular tools used for testing Angular apps
- Jasmine is the testing framework
- Karma is the test runner (browser-based)
- Takes a BDD (Behavioral Driven Development) approach to testing

Organization of .spec.ts Files

- *describe* method used to define a test suite (grouping of tests for feature)
- *it* method(s) used to define individual tests or test specs
- Unit tests often follow what's called AAA (Arrange, Act, Assert) methodology

Organization of .spec.ts Files

- General format is `describe('<suite name>', () => { ... })`; to define suite
- Contained within will be one or more `it('<test name>', () => { ... })`; tests

Organization of .spec.ts Files

```
app.component.spec.ts ×
src > app > app.component.spec.ts > ...
1 import { TestBed } from '@angular/core/testing';
2 import { RouterTestingModule } from '@angular/router/testing';
3 import { AppComponent } from './app.component';
4
5 describe('AppComponent', () => {
6   beforeEach(async () => {
7     await TestBed.configureTestingModule({
8       imports: [
9         RouterTestingModule
10      ],
11      declarations: [
12        AppComponent
13      ],
14    }).compileComponents();
15  });
16
17  it('should create the app', () => {
18    const fixture = TestBed.createComponent(AppComponent);
19    const app = fixture.componentInstance;
20    expect(app).toBeTruthy();
21  });
22
23  it(`should have as title 'unit-test-app'`, () => {
24    const fixture = TestBed.createComponent(AppComponent);
25    const app = fixture.componentInstance;
26    expect(app.title).toEqual('unit-test-app');
27  });
28
29  it('should render title', () => {
30    const fixture = TestBed.createComponent(AppComponent);
31    fixture.detectChanges();
32    const compiled = fixture.nativeElement;
33    expect(compiled.querySelector('.content span').textContent).toContain('unit-test-app app is running!');
34  });
35});
36
```

Setup & Teardown

- In some cases, tests require a particular starting state
- `beforeEach()`; can be used to run common setup before each test
- `afterEach()`; can be used to run common teardown after each test
- Jasmine also supports `beforeAll()` and `afterAll()` forms for setup/teardown before & after all tests

Configure, Run & Debug in VS Code

- Verify configuration in `./karma.conf.js` and `./tsconfig.spec.json`
- May need to set `$CHROME_BIN` environment variable
- Can set inline (for current session) or add to `~/.bashrc` for persistent use
- Encapsulates path to `chrome.exe` (similar setup if using Firefox or Edge)

Configure, Run & Debug in VS Code

- Add launch configuration (.vscode/launch.json)
- Can setup config for debugging through browser and through Karma
- Config becomes selectable at bottom of VS Code window

Configure, Run & Debug in VS Code

- To debug app through browser, run `ng serve`, select debug config for browser, set breakpoint and choose Run | Start Debugging
- `ng test` will be used to run unit tests
- To debug test, run `ng test`, select debug config for tests, set breakpoint and choose Run | Start Debugging (or use “Debug” link in Karma display)

Configure, Run & Debug in VS Code

- To debug app through browser, run `ng serve`, select debug config for browser, set breakpoint and choose Run | Start Debugging
- `ng test` will be used to run unit tests
- To debug test, run `ng test`, select debug config for tests, set breakpoint and choose Run | Start Debugging (or use “Debug” link in Karma display)

Configure, Run & Debug in VS Code

- Use `ng test --no-watch --code-coverage` to run tests and report on code coverage
- Code coverage can help confirm amount of code (and branches of code) being exercised by unit tests

@angular/core/testing Namespace

- Provides access to the *TestBed* class
- Allows us to create a “testing” module that mimics a standard Angular module
- Uses *configureTestingModule()* method to accomplish
- Essentially can detach Angular artifact under test from its host module and attach to testing module

configureTestingModule()

- Uses object with same properties as `@NgModule` decorator
- Allows us to register and configure the test module as we would a live module in the app
- Call `compileComponents()` on the configured testing module to complete setup

compileComponents()

- Compiles components configured in the testing module
- Inlines external CSS files and templates
- Angular CLI will handle this inlining automatically but supports testing with other tools besides the CLI

Testing Components

- @angular/core/testing provides access to *ComponentFixture*
- Wrapper class around an Angular component instance
- Enables interaction with the component and its corresponding selector for test in isolation

Testing Components

- Can use `TestBed.createComponent()` to create an instance of a target component for testing
- With that instance, can test public properties and methods (like any other class)
- Can also use `detectChanges()` to do content tests against rendered view

Testing Components with Dependencies

- In many cases, component under test will have service dependencies
- Goal is to test component in isolation
- Can use the following to help isolate testing to component directly:
 - Stubbing
 - Spying

Stubbing vs. Spying

- Stubbing is utilizing Dependency Injector to inject a stub (or mock) of the dependency vs. the real thing
- Allows more controlled interaction
- Spying is injecting the actual dependency but attaching a “spy” to a method called on component
- Provides options – return mock data or let real call through

- Can use *providers* property of test module and *useValue* version of dependency definition to stub a given service token
- Test setup pulls service reference from root injector which gets mapped to stub
- Can also use *overrideComponent()* if unable to retrieve service from root injector (dependency provided by component injector)

Spying

- Can use the `spyOn()` method to spy on specific method(s) of a service
- Allows verification of arguments passed to actual calls
- Alternatively, can use `createSpyObj()` to stand up a hook for intercepting calls and controlling results

Testing Asynchronous Service Dependencies

- Can use `async` with `whenStable()` or `fakeAsync` with `tick()`
- Can make body of `it` spec method `async` and process assertions using `whenStable()` Promise
- Call `detectChanges()` to trigger `ngOnInit` lifecycle

Testing Asynchronous Service Dependencies

- Can also call `detectChanges()` on async service call completion to trigger data binding and DOM query
- Approach using `fakeAsync` and `tick()` very similar

```
it('should get data from async service dep operation', waitForAsync(() => {
  fixture.detectChanges();

  fixture.whenStable().then(() => {
    fixture.detectChanges();
    expect(fixture.nativeElement.querySelectorAll('tr').length).toBe(7);
  });
}));

it('should get data from async service dep operation diff method', fakeAsync(() => {
  fixture.detectChanges();
  tick(1000);
  fixture.detectChanges();
  expect(fixture.nativeElement.querySelectorAll('tr').length).toBe(7);
}));
});
```

Testing Component Inputs/Outputs

- As part of test, will build a “dummy” component that will act as host for component under test
- Includes utilization of inputs/outputs of component under test
- Tests execute against an instance of the host component with assertions against expected properties of component under test
- Trigger events (e.g., `buttonRef.click()`) from test to exercise output bindings

Testing Services

- Get service instance from injector and test public API
- Goal is testing service in isolation – will mock downstream dependencies
- Common types of service testing:
 - Test synchronous ops
 - Test asynchronous ops
 - Test services with downstream dependencies

Testing Services – Synchronous Ops

- Use `TestBed.inject()` to retrieve instance of service under test
- If provided by root injector, no additional config required in `TestBed.configureTestingModule()`
- Otherwise, can add to providers property of testing module to access
- Exercise method and verify expected results

Testing Services – Asynchronous Ops

- Use same techniques as with synchronous ops to retrieve service instance
- If method to be tested is Observable, subscribe and verify
- Use `done()` at end to signify to Karma that Observable has completed, and expected results can be verified

Testing Services – Downstream Dependencies

- As with components, can mock downstream dependencies to ensure isolation
- However, when testing service that wraps calls to API using *HttpClient*, Angular offers some additional support
- Import *HttpClientTestingModule* in `@angular/common/http/testing` namespace

Testing Services – Downstream Dependencies

- Get an instance of *HttpTestingController* from root injector (defined in same namespace)
- Will be used to “mock out” *HttpClient* calls
- Call service method and subscribe to Observable in test (as normal)

Testing Services – Downstream Dependencies

- Set up expected API calls using *HttpTestingController* (to replace real calls via *HttpClient*)
- Can exercise assertions against the HTTP calls as well
- Execute `flush()` on each mocked HTTP call, optionally providing data to be returned from the call in the service

Testing Pipes

- Create instance of Pipe class in test
- Exercise *transform()* method with test data, verifying expected results

Testing Directives

- Applied to a host component so testing often executed in that context
- Can build test host component and set it plus directive up in test module
- Then test directive using host element, verifying that expected modifications are in place from directive presence
- Also, use defined inputs on directive to test each possible condition

THANK YOU
